VOL. VII.—(DEA—ELD).

Total number of Articles, 673.

PRINCIPAL CONTENTS.

- DEAD SEA. J. L. PORTER, LL.D., D.D., Professor of Biblical Criticism, Belfast
- DEAF AND DUMB. ALFRED LARGE.
- DECALOGUE. Prof ROBERTSON SMITH.
- DEFOE. GEORGE SAINTSBURY.
- DEISM. D. PATRICK.
- DELIII. Hon. W. W. HUNTER, LL.D.
- DELUGE. Rev T. K. CHEYNE, M.A.
- DEMONOLOGY. E. B. TYLOR, LL.D.
- DE MORGAN. W. S. JEVONS, F.R.S., Professor of Political Economy, University College, London.
- DEMOSTHENES. Prof R. C. JEBB.
- DENMARK. E. W. GOSSE, Translator, H.M. Board of Trade, London.
- DENTISTRY. Dr JOHN SMITH.
- DE QUINCEY. J. R. FINDLAY.
- DERBY, EARL OF. W. BROWNING SMITH.
- DESCARTES. Prof. WILLIAM WALLACE, LL.D.
- DEVONSHIRE. R. J. KING.
- DIAGRAMS. Prof. J. CLERK MAXWELL.
- DIALLING. H. GODFRAY, late Fellow of St John's College, Cambridge.
- DIAMOND. Prof. JAMES NICOL.
- DIATOMACEÆ. Rev. EUGENE O'MEARA, M.A.
- DICKENS. Prof. MINTO, Aberdeen University.
- DICTIONARY. Rev. PONSONBY A. LYONS.
- DIDEROT. JOHN MORLEY.
- DIETETICS. Dr T. K. CHAMBERS, Author of "Manual of Diet."
- DIFFUSION. Prof. CLERK MAXWELL.
- DIGESTIVE ORGANS. Prof. WILLIAM TURNER.
- DIPLOMATICS. E. A. BOND, C.B., Principal Librarian of the British Museum.
- DIPTERA. E. C. RYE, Fellow of the Zoological Society.
- DIPHThERIA. Dr J. O. AFFLECK.
- DISTILLATION. Prof. DITTMAR and JAMES PATON.
- DISTRIBUTION. A. R. WALLACE and W. T. T. DYER.
- DIVING. DAVID STEVENSON, C.E.
- DIVORCE. Prof. ED. ROBERTSON, LL.D., M.P.
- DOCKYARDS. F. W. ROWSELL.
- DODO. Prof. ALFRED NEWTON.
- DOG. JOHN GIBSON.
- DOGMATIC. J. S. CANDLISH, D.D., Professor of Divinity, Free Church College, Glasgow.
- DOME. Sir EDMUND BECKETT, Bart., Q.C.
- DOMESDAY BOOK. A. C. EWALD, Public Record Office, London.
- DORIANS. Rev. Sir GEORGE W. COX, Bart.
- DRAGON FLY. R. M'LACHLAN, F.R.S.
- DRAMA. A. W. WARD, Professor of English Literature, Owens College, Manchester.
- DRAUGHTS. HENRY JONES.
- DRAWING. P. G. HAMERTON, Author of "Thoughts about Art."
- DREAM. JAMES SULLY, LL.D.
- DREDGE. Prof. Sir WYVILLE THOMSON, Author of "The Voyage of the Challenger."
- DREDGING. DAVID STEVENSON, C.E.
- DROWNING. Dr HENRY D. LITTLEJOHN.
- DRUIDISM. JAMES MACDONALD, LL.D.
- DRUNKENNESS. Dr GEORGE W. BALFOUR.
- DRUSES. H. A. WEBSTER.
- DRYDEN. Prof. MINTO.
- PUBLIN. E. T. LEFROY, late of *Freeman's Journal*.
- DUDEVANT. FRANOIS STORR, M.A. [Dublin.]
- DUEL. FRANOIS STORR, M.A.
- DUMAS. PERCY FITZGERALD, Author of "Romance of the English Stage."
- DUNDONALD. W. BROWNING SMITH.
- DURER. Prof. SIDNEY COLVIN.
- DURHAM. Rev. J. T. FOWLER, M.A., Hebrew Lecturer, University of Durham.
- DWARF. JOHN DORAN, Ph.D.
- DYCE. W. M. ROSSETTI.
- DYEING. CHARLES O'NEILL, Author of "Chemistry of Calico Printing and Dyeing."
- DYNAMICS. WM. GARNETT, M.A., St John's College, Cambridge.
- EAGLE. Prof. ALFRED NEWTON, F.R.S.
- EAR. J. G. M'KENDRICK, Professor of Institutes of Medicine, University of Glasgow.
- EARTH (FIGURE OF). Col. A. R. CLARKE, R.E., F.R.S.
- EARTHQUAKE. F. W. RUDLER.
- EASTER. Rev. Canon VENABLES.
- ÉCARTÉ. HENRY JONES.
- ECCLIESIASTES. Rev. C. D. GINSBURG, LL.D., Author of "Commentary on Ecclesiastes."
- ECHINODERMATA. F. H. BUTLER, M.A.

ENCYCLOPÆDIA BRITANNICA.

DEA—DEA

DEACON (διάκονος, minister, servant), the name given to the lowest order of minister in the Christian church. From the appointment of the seven Hellenic deacons (Acts vi.) we learn that their duty under the apostles was simply to distribute alms from the public fund. In the early church, however, they soon came to discharge higher functions. They assisted the bishop and presbyter in the service of the sanctuary; in the administration of the Eucharist they handed the elements to the people; they instructed the catechumens, and in some cases baptized; and the archdeacons came to exercise in the 6th century the judicial power of the bishop over the inferior clergy.

In the Church of England the form of ordaining deacons declares that it is their office to assist the priest in the distribution of the holy communion; in which, agreeably to the practice of the ancient church, they are confined to the administering of the wine to the communicants. A deacon in England is not capable of holding any benefice, yet he may officiate as a private chaplain, as curate to a beneficed clergyman, or as lecturer in a parish church. He may be ordained at twenty-three years of age, *anno currente*; but it is expressly provided that the bishop shall not ordain the same person a priest and deacon on the same day. In Presbyterian churches, as in apostolic times, the deacons have charge only of the pecuniary affairs of the congregation. In the Roman Catholic Church it is the deacon's office to incense the officiating priest or prelate; to lay the corporal on the altar; to receive the paten or cup from the subdeacon, and present it to the person officiating; to incense the choir; to receive the pix from the officiating prelate, and to carry it to the subdeacon; and at a pontifical mass, when the archbishop gives the blessing, to put the mitre on his head, and to take off the archiepiscopal pall and lay it on the altar.

Deaconess.—This was the title of a ministry to which women were appointed in the early church, whose duty it was to perform certain functions towards female catechumens during the ceremony of baptism by immersion, which could not so well be performed by the deacons. Their age was at first fixed at sixty years, but it was afterwards reduced to forty years, and no married woman was eligible to the office. Abuses gradually became prevalent amongst the deaconesses, which led to the suppression of

their ministry in the Latin church in the 6th century. The office was abolished in the Greek church in the 12th century.

DEAD SEA, the largest lake in Palestine, and physically, as well as historically, among the most remarkable in the world. It is called in Scripture *The Salt Sea* (Gen. xiv. 3), *The Sea of the Plain*, or more correctly of the *Arabah* (Deut. iii. 17), and *The East Sea* (Ezek. xlvii. 18). Josephus calls it the *Asphaltic Lake* (B. J. iii. 10, 17), a name adopted by classic writers in allusion to the bitumen, or asphaltum, which abounds in its basin. Jerome gave it the name *Dead Sea* because its waters are fatal to animal life, and in the Talmud it is called the *Sea of Sodom*. Its common name among the inhabitants of Palestine is *Baheiret Litt*, "The Sea of Lot."

The sea is 46 miles long, and varies from 5 to 9 in breadth. Its bed is the lowest part of the great valley of the Jordan; and its surface has a depression of no less than 1308 feet beneath the level of the ocean. The Jordan valley itself, for a distance of about 80 miles to the northward and 30 to the southward, is also below the level of the ocean. The general contour of the sea is an elongated oval, with a number of bold promontories and deep bays along the western shore, and a large, low peninsula on the south-east. It is shut in on the east and west by parallel ranges of mountains which rise steeply, and in some places in precipices of naked rock, from the water. The western range is the mountain chain of Judah, and is composed of white limestone intermixed with yellow and reddish strata. Its whole eastern slopes are bare, rugged, and desolate, forming that wilderness in which David found an asylum, in which the Baptist preached, and in which our Lord was tempted. The average height of the cliffs along the shore is about 2000 feet; but they are deeply fissured by torrent beds, which are all dry in summer. There are, however, a few fountains in the glens and near the shore, the most celebrated of which is the *Biblical Engedi*. At the north-west curve of the sea are extensive salt marshes, and at the south-west is a range of hills of rock salt, 7 miles long and 300 feet high, called *Khashm Usdom*, "The ridge of Sodom." On the south of the sea lies a low marshy plain, partially covered with jungles of reeds, tamarisk, and broom.

The mountain range along the eastern side of the Dead Sea is the sustaining wall of the tableland of Moab, which has an elevation of about 2800 feet, and is therefore 4000 feet above the lake. At the southern end the range is composed of red sandstone, a continuation of the "red" mountains of Edom. At the valley of Kerek the sandstone gives place to limestone; but further north it again appears in thick strata below the limestone. The range is intersected by the deep and wild ravines of Kerak (the *Kir-Moab* of the Bible), Mojob (the ancient *Arnon*), and Zerka Main (*Maon*). A few miles from the mouth of the latter are the warm springs of Callirrhoe, famous in Jewish and Roman times. A copious stream of warm sulphureous water flows into the lake between stupendous cliffs of sandstone. North of Zerka Main the cliffs along the shore are sandstone, but higher up the limestone overlies the sandstone, while dykes and seams of old trap-rock also occur.

At the mouth of the ravine of Kerak, on the south-east of the sea, is the peninsula of *Lisân*, "The Tongue." Its neck is a strip of bare sand about 3 miles broad. In form the peninsula bears some resemblance to the human foot, the toe projecting northward up the centre of the sea. Its length is about 9 miles. It is a post-tertiary deposit of layers of marl, gypsum, and sandy conglomerate; the surface is white and almost destitute of vegetation.

The Jordan enters the lake at the centre of its northern end, and has on each bank a low alluvial plain, now a desert, and mostly coated with a white nitrous crust. In fact the whole circuit of the lake is wild, dreary, and desolate. Ridges of drift mark the water-line, which rises a few feet in spring, when the Jordan, fed by the melting snows of Hermon, flows in full stream. The drift is composed of broken canes and willow branches, with trunks of palms, poplars, and other trees, half-imbedded in slumy mud, and covered with incrustations of salt. Lying in a deep cavity, shut in by naked white hills, exposed during the long summer to the burning rays of an unclouded sun, nothing could be expected on the shores of the Dead Sea but sterility. Yet here and there on the low plains to the north and south, and on the eastern and western sides, wherever a little fountain springs up, or a mountain streamlet flows, there are thickets of willow, tamarisk, and acacia, among which the birds sing as sweetly as in more genial climes. The Arab also pitches his tent beside them, and sometimes cultivates a few patches of grain and tobacco. The heat causes such excessive evaporation that though the Jordan and other smaller streams fall into the lake the water seems to be gradually decreasing. The marshes along the shore, especially to the north and south, emit pestilential exhalations during summer and autumn which are fatal to strangers, and which make the inhabitants of Jericho, and the few poor tribes who pitch their tents in the surrounding territory, weak and sickly. They are degraded and immoral also, as were their progenitors in the "cities of the plain."

The only ruin of note close to the Dead Sea is the fortress of Masada, on a cliff on the western shore, opposite the peninsula of *Lisân*. It was the scene of the final struggle between the Jews and the Romans after the destruction of Jerusalem by Titus. At Engedi there are a few ruins; and also at Ain-el-Feshkhah on the north-west, and a little peninsula near the mouth of the Jordan. The cities of Sodom and Gomorrah have entirely disappeared. Their site is disputed, for some hold that they stood near the northern end of the lake, while others affirm that they have been situated at the southern end.

The Dead Sea is divided into two sections, extending from the mouth of the Jordan to the north, is 33 miles long, and is a regular basin, the sides descending steeply and uniformly

to a depth of 1308 feet. The southern section is shallow, the greatest depth of the channel between the peninsula and the western shore being only 13 feet, while no part of the lake south of the peninsula is more than 12 feet, and most of it only 3 or 4 feet deep.

The water is intensely salt and bitter, and its density is so great that the human body will not sink in it. The following is an analysis of water lifted by Captain Lynch from a depth of 1110 feet, the specific gravity of which was 1.227:—

Chloride of calcium	3.107
Chloride of magnesium	14.859
Chloride of sodium	7.855
Chloride of potassium	0.658
Sulphate of lime	0.070
Bromide of potassium	0.137
Total	26.416

The presence of so much saline matter is accounted for by the washings of the salt range of Sodom, the numerous brackish springs along the shore, and the great evaporation. The reports of early travellers, however, regarding the Dead Sea were to a great extent fabulous. They represented it as an infernal region, its black and fetid waters always emitting a noisome vapour, which being driven over the adjoining land destroyed all vegetation; they also stated that no birds could fly over it. All this is untrue, the water is as transparent as that of the Mediterranean, and a bath in it is both pleasant and refreshing.

The historical notices of the Dead Sea extend back nearly 4000 years. When Lot looked down from the heights of Bethel, he "beheld all the plain of the Jordan that it was well watered, before the Lord destroyed Sodom, even as the garden of the Lord" (Gen. xiii. 10). The region is further described as a "deep valley" (*Emek*, Gen. xiv. 3, 8), distinguished by "fertile fields" (*Siddim*). The aspect now is entirely different. There must have been a lake then as now, but it was smaller, and had a margin of fertile plain, especially on the southern end, "as thou comest unto Zoar." In the narration of the capture of the cities of the plain by the Eastern kings, it is said that they were situated in the "vale of Siddim," which was full of "bitumen (slime) pits." When the cities were destroyed, "the Lord rained upon Sodom and upon Gomorrah brimstone and fire from the Lord out of heaven," and Abraham from the mountain ridges "looked toward Sodom, and toward all the land of the plain, and, lo, the smoke of the country went up as the smoke of a furnace" (Gen. xix. 24, 28). The sacred writer further asserts regarding the vale of Siddim that it became the Salt Sea, or was submerged; and consequently it now forms part of the bed of the lake.

These events entirely changed, as it would seem, both the political and physical condition of the whole region. Upon the plains originally existing round the sea Gentile and Jewish records combine in placing the earliest seat of Phœnician civilization. "The Tyrians," says Justin, "first dwelt by the Syrian lake before they removed to Sidon." Sodom and Gomorrah are mentioned as the first cities of the Canaanites; and when Lot went down from Bethel "the cities of the plain" formed a nucleus of civilized life before any city, except Hebron and perhaps Jerusalem, had sprung up in central Palestine. The great catastrophe in the days of Abraham changed the aspect of the country, and gave a death-blow to its prosperity. With the exception of the village of Engedi, and the small town of Jericho, the circuit of the Dead Sea appears to have remained ever afterwards almost without settled inhabitants.

Recent researches, especially those of M. Lartet, the Duc de Luyne, and Canon Tristram, have contributed greatly to our knowledge of the physical geography of the Dead Sea basin. It is now shown from the geological

structure of the watershed in the valley of the Arabah to the south, and from the direction of the lateral ravines which fall into the great Jordan valley, that the river Jordan could never have run into the Red Sea. The depression of the Dead Sea is 1308 feet, while the elevation of the watershed is 787 feet, and the action which upheaved the watershed occurred at the same geological period which gave to the whole of Palestine its present form. The formation of the Jordan valley M. Lartet accounts for in this way. At some remote period a fracture took place in the upper strata in this region, extending north and south. In consequence of the unequal strength of the strata the western side of the fracture sank, occasioning the abrupt dip observable in the strata on the western side of the valley, and the great depression of the valley itself; while the eastern side of the fracture remained *in situ*, showing at various places along the eastern shore of the Dead Sea a vertical section through the limestone and sandstone. The basin of the Dead Sea has thus been since its foundation a reservoir for the rainfall; while its saltness originally proceeded from the salt-spring and hills, and gradually increased by evaporation.

Deposits of great depth have accumulated in the whole valley since its formation, composed of beds of gypsum, marl, flint, and alluvium, similar to those now in process of formation at the bottom of the Dead Sea. They show that at one period the whole Jordan valley was under water; while the sides of the valley indicate successive stages in the fall of the water from the time when its surface was on the level of the ocean down to the present age. The hill-sides and strips of plain on both the eastern and western banks of the Dead Sea are marked by a series of terraces or shore-lines. The highest has an elevation corresponding to the level of the Mediterranean. About 230 feet above the present level of the lake there is another shore-line, marked by a strip of alluvial marl adhering to the rocks and cliffs, particularly at the north-west angle. The deposit is mixed with shells of existing species, layers of gypsum and gravel. This line would correspond with the general level of the great valley northward, through which the river Jordan has cut a deep channel. There are, besides, in the ravines which descend to the lake, comparatively recent deposits, reaching up their sides in places to a height of 400 feet, and then sloping down in a series of terraces to the present level of the lake, showing the gradual depression of the water. Tristram also remarked on the western shore "no less than eight low gravel terraces, the ledges of comparatively recent beaches, distinctly marked. The highest of them was 44 feet above the present sea-level."

Many traces of volcanic action, both remote and recent, have been observed in the basin of the Dead Sea, such as trap dykes, and hot sulphur and brackish springs. Tristram describes a valley at the northern end of the salt range of Sodom, in which there are

"large masses of bitumen mingled with gravel. These overlies a thick stratum of sulphur, which again overlies a thicker stratum of sand so strongly impregnated with sulphur that it yields powerful fumes on being sprinkled over a hot coal. The bitumen, unlike that which we pick up on the shore, is strongly impregnated with sulphur. Above all, it is calcined, and bears the marks of having been subjected to extreme heat. So far as I can understand this deposit, if there be any physical evidence left of the catastrophe which destroyed Sodom and Gomorrah, or of similar occurrences, we have it here. The whole appearance points to a shower of hot sulphur, and an eruption of bitumen upon it, which would naturally be calcined and impregnated with its fumes, and thus at a geological period quite subsequent to all the diluvial and alluvial action of which we have such abundant evidence. The catastrophe must have been since the formation of the valley, and while the water was at its present level,—therefore, probably during the historic period." (*Land of Israel*, pp. 355, sq.)

Tristram applies the above-observed facts to the solution

of the great historical question about the destruction of the cities of the plain in the following manner.—

"Setting aside all preconceived notions, and taking the simple record of Genesis xix. as we find it, let us see whether the existing condition of the country throws any light on the Biblical narrative. Certainly we do observe by the lake sulphur and bitumen in abundance. Sulphur springs stud the shores, sulphur is strewn, whether in layers or in fragments, over the desolate plains, and bitumen is ejected in great floating masses from the bottom of the sea, oozes through the fissures of the rocks, is deposited with gravel on the beach, or appears with sulphur to have been precipitated during some convulsion. We know that at the time of earthquakes bitumen seems to be detached from the bottom of the lake. Everything leads to the conclusion that the agency of fire was at work. The kindling of such a mass of combustible material, either by lightning from heaven, or by other electrical agency, combined with an earthquake ejecting other bitumen or sulphur from the lake, would soon spread devastation over the plain, so that the smoke of the country would go up as the smoke of a furnace" (*Land of Israel*, p. 359).

Here we have to do only with physical facts and appearances. A mass of burning sulphurous matter might be ejected from some open crater, as is often the case with Vesuvius, and this, falling upon the cities and the bituminous plain around them, would produce just such a form of conflagration as Abraham is stated to have seen. The valley may then have sunk a few feet, and become submerged. This, it is true, is mere theory, it is a theory, however, suggested, and to a large extent confirmed, by the physical aspect of the country, and the careful observations of travellers around the lake. The subject is not one for vague speculation, and much less for dogmatic assertion. The problems which the Dead Sea present must be solved, if they are ever to be solved, by scientific research.

It is not strange that the Dead Sea has never been navigated to any extent. It seems probable from the statement of Josephus (*Ant. ix. 1, 2*) that the Moabites crossed it to invade Judah, and he tells us the Romans used boats against the fugitive Jews (*B. J. iv. 7, 6*). Costigan was the first in modern times to navigate it, going from the mouth of the Jordan to the peninsula of Lisân in the boat by which he had come from Tiberias. He afterwards died of fatigue and exhaustion. In 1837 Moore and Beek conveyed a little boat from Joppa, and visited some points. Ten years later Lieutenant Molyneux took a boat to the peninsula, and his life was also sacrificed. The expedition of Lynch was far more successful, and he was the first thoroughly to examine the shores, and to determine the depths by soundings. Several of his party took the fever which is so fatal, and one died. Winter is the proper season for such researches. Rain seldom falls; and the air during the depth of winter is fresh, and cold almost unknown.

The following are the leading works which treat of the Dead Sea—Robinson, *Physical Geography of Palestine*; De Sauley, *Voyage autour de la Mer Morte*; Lynch, *Official Report to United States Government*; Ritter, *Comparative Geography of Palestine*, vol. in appendix 1. (J. L. P.)

DEADLY NIGHTSHADE. See BELLADONNA.

DEAF AND DUMB. It is a not uncommon supposition that deaf mutes are dumb on account of some vocal or organic defect, whereas the dumbness arises, with very rare exceptions, from the deprivation of hearing caused by some natural or accidental disease. Where partial or total dumbness exists with the sense of hearing perfect, it will be generally found to proceed either from great nervous debility or from some mental derangement, and not, as is often supposed, from some defect in the vocal organs, which in the congenitally deaf, with hardly an exception, are in their normal condition. Many children who are enumerated as congenitally deaf have the sense of hearing to a greater or less degree, but not to such an extent as to be of service to them in the acquisition of language. It is remarkable that the defect of hearing is not generally dis-

covered till an advanced period of childhood, and though the child remains mute the real cause is neither readily acknowledged nor properly attended to. Children who have lost their hearing after the acquisition of the power of speech cannot be included in the class of deaf mutes; the impression which language has made on their minds gives to them a marked superiority over those who are deaf from birth.

Such a calamity as the deprivation of hearing must be productive of great and varied disadvantages, as it totally excludes the mind from an extensive class of ideas and associations. It is then not to be wondered at that this state of social isolation should occasionally give rise to moroseness and despondency, and that external objects should inspire little sense of surprise or admiration. They are simply objects recognized by their form, colour, and texture, and the emotions they raise are different both in character and in intensity from those experienced by hearing children. This physical defect has not, however, any necessary connection with the presence or absence of intellectual capacity, or with the active principles of our nature. There is only the want of one of the natural and most important avenues to intellectual development, with its primary consequence of dumbness, and its secondary one of social isolation. Still, the denial of all such knowledge as can be derived through the medium of the ear is somewhat atoned for by the quickened influence of other senses, especially that of sight. Thus the visible marks of attention the deaf and dumb receive from others,—their caresses, frowns, and smiles,—all make a corresponding impression on their tender minds, and as they grow older they watch the looks and gestures of those near them with a keenness unknown to other children, so that the slightest change of expression does not escape their observation. Their affections are stimulated and their passions excited much in the same way as in other children.

The proportion of children born deaf was formerly supposed to be much smaller than it really is. Cases have come to be known in largely increased numbers since institutions for the deaf and dumb have been established, and such statistical tables as are given in this article suggest the incorrectness of the popular supposition. The institutions which have been founded on their behalf have not only diffused correct information concerning their number, but by the gratifying success of the educational methods adopted have greatly contributed to dissipate prejudicial notions concerning their capacity to receive instruction, and to direct public sympathy towards the claims of this class. The latter office it is still needful that they fulfil, for prejudices yet exist against deaf mutes,—one of these being the general supposition that they are very vicious and hot-tempered. It may be admitted that some of them are so; and it may even be granted that the proportion of mutes with such dispositions is as high as in any other class of afflicted persons, for in the case of the deaf and dumb there are undoubtedly special circumstances of early life which tend in no small degree to such a result. The total inability of parents to deal with their abnormal peculiarities must be included among the causes which prejudicially affect their dispositions, and overshadow attractive features of their character; and the kindly-intended interference of neighbours with the parental management often proves morally injurious to them. Their discernment of right and wrong is equal to that of other children, and hence, when neighbours unwisely seek to screen them from merited punishment, a spirit of insubordination is excited, and sullenness or passionateness is induced. It should therefore be the parents' utmost endeavour, when punishment is to be administered, to treat these children impartially. It is most desirable also that external circumstances should be as favourable to them as possible, and

everything calculated to pollute their uncultivated minds kept from their acute powers of observation.

Causes—The causes assigned for congenital deafness are consanguineous marriages, hereditary transmission, weak constitutions of parents, scrofula, climate, and the ill-health of the mother at a certain period of life. There is necessarily difficulty in ascertaining the real cause of deafness. That difficulty has its ground in the unwillingness of parents to admit that their children were born deaf. Their deafness is often attributed to some infantile disease, though the defect is congenital. On the other hand, when they have lost the sense of hearing at an early age, they may be included among the congenitally deaf. But all institutions for the deaf and dumb contain instances which illustrate scientific investigations, and establish the position that such causes as those now alluded to tend to induce and perpetuate the disease of deafness. In all cases of congenital deafness it will be found that there exists some disorganization of the organ of hearing itself, some obstruction in the internal ear or compression of the auditory nerve, whereby the vibrations of the ear are prevented from producing the required effect upon the internal parts of the ear, or from being communicated to the brain.

After-birth or acquired deafness occurs at all ages, and has its origin in such diseases as small-pox, measles, typhus, convulsions, paralysis, hydrocephalus, and other affections of the brain, and "scarlatina, which more frequently than any other disease leaves the patient deaf, in consequence of the inflammatory state of the throat extending to the internal ear, causing suppuration and destruction of the delicate apparatus on which hearing depends, such being the case, especial attention should be directed during the course of the disease to the state of the throat, so as to prevent if possible the inflammation extending." Vaccination has been the means of greatly decreasing the cases of deafness; and doubtless, as sanitary laws become more general, the introduction of perfect sewerage, pure water, and good ventilation, will all tend to lessen the liability to those zymotic diseases upon which deafness supervenes. Amongst other causes of deafness are cold, and severe blows or falls upon the head. It has been ascertained that the proportion is about 60 per cent. congenitally deaf to 40 per cent. accidentally so, and the census returns for 1871 show that of the 1054 inmates of 12 institutions of England and Wales 63 per cent. were congenitally deaf. Consanguineous marriages are perhaps the most fertile source of deafness, which fact is established by the numerous cases of deaf children who are the offspring of first cousins. It is not only so in England, but in other countries of Europe and in America. Dr Buxton says, "In an inquiry which I made some time ago, I found that about every tenth case of deafness resulted from the marriage of cousins." The Irish Commissioners' Report for 1871 says, "Too close consanguinity in the intermarriage of relatives, and also hereditary predisposition, have long been supposed to be causes of congenital deaf-muteism." The results obtained by the census of 1871 tend to establish these suppositions.

The following table from census returns for Ireland exhibits the amount of deaf-muteism where consanguinity of parents existed:—

	Congenital Deaf Cases	Acquired Deaf Cases	Total
First cousins	80	5	85
Second cousins	60	3	63
Third cousins	31	1	32
Fourth cousins	7	0	7
Fifth and sixth cousins .	14	0	14
	192	9	201

Thus we find that, in 201 instances of relationship between the parents of mutes, 85 were in the degree of first cousins, 63 in that of second, 32 in that of third, 7 in that of fourth, and in 14 they were more remotely related.

Dr Bondin, at a meeting of the Academy of Sciences, Paris, noticed the following striking result of such unions:—

"Two brothers in perfect health, and well constituted men, had married two sisters, their consanguineans. The elder brother has had several children, one of whom is deaf and dumb. The other brother has had six children, the first, third, and fifth of whom can hear, while the second, fourth, and probably the sixth (an infant) are deaf and dumb."

The report of Dr S. M. Bemiss of Louisville, Kentucky, to the American Medical Association on the subject of the influence of marriages of consanguinity on offspring and records the following results of 833 such marriages:—

Of the 3942 children of those marriages 1134 were defective in one way or another, viz.—deaf and dumb, 145; blind, 85; idiotic, 308; insane, 38, epileptic, 60; scrofulous, 300; and deformed, 98; 883 died young, and the writer concludes by remarking, "I feel satisfied, however, that my research gave me authority to assume that over 10 per cent of the deaf and dumb, and over 5 per cent of the blind, and nearly 15 per cent of the idiotic, in our State institutions for subjects of those defects, and throughout the country at large, are the offspring of kindred parents, or of parents themselves the descendants of blood intermarriages."

Another great cause of deafness is hereditary transmission. "It has clearly been ascertained," says Dr Harvey (*On the Ear*), "that the most common cause is a strumous and delicate habit of body, generally hereditary."

The subjoined table from the census returns for Ireland in 1871 proves that deaf-muteism is often transmitted by hereditary taint or family peculiarity. The table is divided into two sections,—the first showing where the disease is transmitted by the father, the second by the mother.

Mute relations on Father's side.

No. of Deaf Mutes in each family	Grandfather.	Grandmother.	Grandfather.	Grandmother.	Granduncle.	Grandniece.	Father.	Uncle.	Aunt.	Cousin.	Total.
One . . .	1	1	5	2	5	12	8	50	93
Two . . .	1	4	4	1	16	26
Three	1	1	1	2	10	16
Four	1	2
Five	2	2
											130

Mute relations on Mother's side.

No. of Deaf Mutes in each family	Grandfather.	Granduncle.	Grandniece.	Mother.	Uncle.	Aunt.	Cousin.	Total.
One . . .	12	3	2	9	6	12	33	67
Two	3	..	2	2	3	23	33
Three	1	..	1	..	7	9
Four	2	1	..	3
Five	2	2
								114

The Commissioners' Report is as follows:—

"Although it has been shown that muteism is transmitted by hereditary taint, yet it very seldom descends directly from the parent to the offspring, which is manifest from the following results of the inquiry made respecting the marriage state of the congenitally deaf. After a minute investigation of this subject, we find 115 instances, 77 males and 38 females, of the marriages of congenital deaf mutes where either one or both parties were affected. In 81 instances we ascertained that only one of the parties was congenitally deaf, and that 234 children, none of whom were deaf and dumb, resulted from 67 such marriages; in the remaining 14 instances

there was no issue. We find four instances of the marriage of a congenital deaf mute with an acquired deaf mute, from three of which 7 children resulted, one of whom was deaf and dumb. There were 13 instances of the intermarriage of persons both of whom were deaf and dumb, and from 12 of these marriages 44 children resulted, of whom only one was deaf and dumb, and another was deaf only. The grand-parents of the former on the mother's side, and a grand-uncle of the father's, were also deaf and dumb. Of 315 children resulting from 87 of the afore-mentioned marriages, only two were deaf and dumb and one deaf only. In a case of the intermarriage of congenital deaf mutes, although the husband's parents were second cousins and the wife's also related, and her sister deaf and dumb, yet none of the 8 children resulting from the marriage were in any way afflicted."

The Principal of the New York Institution says, "We can show that it is much the most common for the children of deaf and dumb parents to possess the faculties of which their parents are deprived, still, although the offspring may not be defective, they may likely inherit that peculiar taint of constitution by which the disease will be transmitted to future generations, which is so often the case."

Mr Turner, in a paper on *Hereditary Deafness*, gives the following table:—

Class	Parents	No. of Families	No. of Children Deaf	No. of Children Hearing	Total
1	One hearing and one congenitally deaf	30	15	77	92
2	One incidentally and one congenitally deaf	56	6	120	126
3	Both congenitally deaf	24	17	40	57
		110	38	237	275

From this it appears that in 86 families with one parent a congenital deaf mute there were 218 children, of whom 21 were deaf and dumb, or about one-tenth of the whole. In the 24 families with both parents congenital deaf mutes there were 57 children, of whom 17 were deaf and dumb, or about one-third of the whole. The proportion of deaf-mute children of parents both congenitally deaf is thus more than three times greater than of parents only one of whom is congenitally deaf.

The subjoined table shows the proportion of the families, constituted as above, who had deaf-mute children in them:—

Class	Parents.	Families.	Families
1	One hearing and one congenitally deaf	30	One or more deaf and dumb in 5
2	One incidentally and one congenitally deaf	56	" " 4
3	Both congenitally deaf	24	" " 9

The proportion of families having one congenitally deaf parent, with at least one deaf-mute child, is about one-tenth of the whole, while the proportion of the families having both parents congenitally deaf with a deaf-mute child or children is more than one-third of the whole. The above tables show the amount of deafness transmitted by the marriage of one congenitally deaf with one hearing person. The cases of deafness resulting therefrom are only one-tenth of the whole, whereas those from the intermarriage of deaf mutes are about one third. Similar results could be obtained from reports of many of the institutions, but from what has already been stated on this cause of deafness, it appears that, while there is sufficient reason to justify the prohibition of the intermarriage of deaf mutes, the exceptional cases of deaf mute offspring as the result of unions of deaf mutes with hearing persons would not justify interference in such marriages.

History of Instruction—In early times, it was an opinion maintained, even by philosophers, that the education of the deaf and dumb was not possible. It was then believed that language could only be acquired through the medium of the ear. The couplet of Lucretius is well known—

"To instruct the deaf no art could ever reach,
No care improve them, and no wisdom teach."

Parents, influenced by this belief, allowed their children to grow up without culture. They were abandoned to themselves, and exiled from the community of rational beings. To such a culpable extent was this prejudice carried, that it has been the practice in some countries to destroy children who remained at three years of age incapable of either hearing or speaking, and by the code of Justinian deaf mutes are declared to be incapable of civil acts. In France, the very birth of such children was accounted a sort of disgrace to the family from which they sprang, and the duties of humanity were deemed to extend no further in their behalf than to the maintenance of their animal existence, while they were carefully secluded from the eyes of the world either within the walls of the cloister or in some hidden asylum in the country. Abandoned thus early to their fate, and regarded as little better than idiots, it is not surprising that their future behaviour should have been such as might seem to justify the erroneous views which had prompted this ungenerous treatment. The progress in the art of instructing the deaf and dumb was in consequence greatly retarded, attempts to instruct them were scarcely known, and no school was established till the middle of the 18th century. In the 4th century, St Augustine, influenced by the dictum of Aristotle, expresses his unfavourable opinion respecting their ability to obtain any religious knowledge, remarking, "that deafness from birth makes faith impossible, since he who is born deaf can neither hear the word nor learn to read it." But in this enlightened age it has been fully proved that the neglect and forgetfulness to which these outcasts were formerly consigned were founded on very mistaken notions of their mental capacities.

The first instance of a deaf mute being instructed is mentioned by Bede in 685. No other case is met with till some centuries afterwards. Rodolphus Agricola, of Heidelberg, who was born in 1442, and died in 1485, makes mention in his *De Inventione Dialectica*, of an educated deaf mute; but this instance, and probably others, were discredited on the ground of their impossibility. Jerome Cardan, a native of Pavia, born in 1501, took a more philosophical view of the subject, and says, "Writing is associated with speech, and speech with thought, but written characters and ideas may be connected without the intervention of sounds," from which he further argues that "the instruction of the deaf is difficult, but it is possible." It was no doubt this enlightened view that gave to the education of the deaf and dumb its first and greatest impetus. A Spanish Benedictine monk of the convent of Sabagun in Spain, named Pedro de Ponce, who was born in Valladolid in 1520 and died in 1584, is the first person who is recorded to have instructed the deaf and dumb and taught them to speak. He was fifty-six years old when Jerome Cardan died, and he had no doubt, from his association with Cardan, imbibed his principles. He has, however, left no work upon the subject, though it is probable that the substance of his method is contained in a book of Bonet, secretary to the constable of Castile, printed at Madrid in 1620 under the title of *Reduccion de las letras y artes para enseñar á hablar á los mudos*. In the time of Bonet the teaching of the deaf and dumb was becoming more general and was entered upon by several persons, both in Italy and in England. Dr John Bulwer, an English physician, and Dr Wallis, professor of mathematics in the university of Oxford, were both engaged in the work in England about the same time, though it is not accurately known to whom the honour of being its prime mover is due. The former published a treatise on the education of the deaf and dumb in 1648, several

years before Dr Wallis's valuable and able work had appeared. In the year 1669, some years after Dr Wallis's writings and practice of instructing the deaf and dumb had been known, Dr W. Holder, rector of Bletchington, published a work entitled *Elements of Speech, with an Appendix concerning Persons Deaf and Dumb*; in 1670 George Sibscote issued a *Treatise concerning those who are Born Deaf and Dumb*; and in the year 1680 George Dalgarno, a native of Aberdeen, published an able and philosophical work, under the title of *Didascalocophus, or the Deaf and Dumb Man's Tutor*, which was reprinted some years ago by the Mantland Club. This last-named work is considered by Professor Porter as "one of the most remarkable and important productions in the whole history of the art." To an early work of his, entitled *Ars Signorum*, both Bishop Wilkins and Dr Wallis were indebted, but they never mention his name. This ungenerous silence unfavourably contrasts with Leibnitz's frequent commendation of the work. Above all others, John Conrad Amman, a Swiss physician living at Amsterdam, distinguished himself by his ingenious and successful method of teaching the deaf and dumb to speak. He reduced the work to a fixed art or method, which he published in his *Surdus Loquens*, 1692, whereof an English translation was afterwards published by Daniel Foot.

In France the work of teaching the deaf and dumb was late in receiving the attention it deserved, in consequence of the still prevalent doubt as to its practicability, although many instances of success in other countries were generally known. It was not till about the middle of the 17th century that the subject was taken up with any interest. Vauvenargues, a Father of the Christian Doctrine, made some attempts to alleviate the condition of the deaf and dumb, but his work was cut short by death. After him came Ernaud, Rodriguez Pereira, the Abbé Deschamps, and the Abbé de l'Épée. In Silesia, at the beginning of the 18th century, W. Kerger established his method on the principles of John C. Amman; and in 1718 George Raphael, a German, and contemporary with Kerger, published the system he had carried out in the education of three deaf mutes in his own family. All this interesting work had been accomplished before any public school for the deaf and dumb had been established; and it was not till 1760 that Abbé de l'Épée started the first school in Paris. About the same time Thomas Braidwood opened a school in Edinburgh; and in 1778 Heinicke in Germany founded another at Leipzig under the patronage of the Government, where he pursued the system of articulation and lip reading which forms the basis of instruction in the German schools of the present day. Thomas Braidwood made himself famous by his remarkable success. He was visited by Dr Johnson when on his tour to the Hebrides, who expressed himself highly gratified with the success in what he considered a great philosophical curiosity. In 1783 Braidwood left Edinburgh and opened a school at Hackney, near London, where he continued his arduous duties till 1806, when he died. Two of his sons became instructors of the deaf and dumb. A school was opened in Edinburgh by one of them in 1810, and the other started a school at Birmingham in 1825. In the year 1792 the first public school in Great Britain for the gratuitous education of the deaf and dumb was opened in Bernouddsey, London, of which Dr Watson, the nephew of Thomas Braidwood, was for thirty-seven years the head instructor. Since the above date (1792) schools have been established in many of the principal towns of Europe and America.

Methods of Instruction.—All the institutions and schools for the education of the deaf and dumb employ one or other

of the two following methods—(1) that in which the sign language and manual alphabet form the basis of instruction, with articulation and lip reading to a greater or less extent, but, as a rule, only for the semi-mute, semi-deaf, and those of the congenitally deaf of good capacities, and who show an aptitude for it; and (2) that in which articulation and lip reading form the basis of instruction, and the sign language and the manual alphabet are used more or less as a means to the end. The former is the more general, and is carried out in all the schools of the United Kingdom (although in the London Asylum articulation and lip reading are professedly and systematically taught to every pupil), in America, and in some of the Continental schools. The latter is the one chiefly employed in the German and Austrian schools, and is followed in one or two private schools in London.

The signs in use in all schools are of two kinds—the natural, and the conventional or arbitrary. The former are those with which all deaf mutes are familiar before coming to school, and which they use in ordinary intercourse with their friends. The latter are chosen and systematized by the teachers of the several schools, and, in combination with the natural signs, are employed to convey ideas of a complex nature. Every action, the visible part of which can be imitated by gesture, admits easily of being so expressed, as the action of eating by lifting the hand to the mouth followed by the motion of the jaws, and of sleeping by closing the eyes and reclining the head; the expression of different passions, of approbation or disapprobation, of surprise, curiosity, &c., may all be signified very intelligibly by modifications of the countenance. "It is in this simple manner," observes Dr Watson, "that two or more deaf persons are enabled to hold instant converse with each other though brought together from the most distant parts." Thus far these signs may be termed natural, but the naturally deaf do not stop with this language of pantomime. When they are fortunate enough to meet with attentive companions, especially where two or more deaf persons happen to be brought up together, it is astonishing what approaches they will make towards the construction of an artificial language. By an arbitrary sign fixed by common consent, or accidentally hit upon, they will designate a person, place, or thing, and this sign is ever after used by them as a proper name. It is impossible to give a verbal description of those signs, because they are as various as the fancies and circumstances of their inventors. Yet being grafted on the parent stock of natural and universal signs, they may in some measure be regarded as different dialects of the same language. But since it would be impossible by means of natural signs alone to convey to the minds of the deaf and dumb ideas of a complex nature, recourse must be had to that system of signs known as conventional or arbitrary. These signs have been extended and systematized on natural and philosophical principles by the several teachers of the deaf and dumb, and they differ in degree in all schools. It would be impracticable to maintain the same system of signs throughout, even should such be desirable, but it is of the utmost importance that those in use in each school should be so cultivated as to prevent any confusion of ideas by the improper use of them. It is by their aid chiefly that all instruction is carried on, and, as used by missionaries for the deaf and dumb, they are remarkably serviceable, there being always to be found, in an assembly of deaf mutes, many whose minds cannot be reached by any other means. Attempts are often made in the institutions for the deaf and dumb to dispense with signs, and to use the manual alphabet alone after the pupils have acquired a certain proficiency in language. Although this would prove of immense educational advantage, attachment to the natural language of signs is so strong that it has always

been found as impracticable to make the change as to substitute articulation and lip reading. Signs to the educated deaf and dumb should be as crutches to the halt—to be used only when occasion requires,—otherwise their constant use will tend to enfeeble rather than strengthen the intellect. In the sixth report of the American Asylum at Hartford, Connecticut, the following is given as an answer of a deaf mute to the question, "Which do you consider preferable—the language of speech or of signs?"—

"I consider to prefer the language of signs best of it, because the language of signs is capable of to give me elucidation and understanding well. I am fond of talking with the deaf and dumb quickly, without having the troubles of the voice. Therefore the language of signs is more still and calm than the language of speech, which is full of falsehood and trouble."

The Abbé de l'Épée, to whom teachers of mutes are greatly indebted for the methodical and ingenious system of signs, altogether mistook their function as a means of educating the deaf and dumb and in consequence his method failed entirely. He gave to each word its peculiar and appropriate gesture in the natural order of the language; and by the intervention of these gestures he succeeded in enabling his pupils to transcribe whole pages of the most abstract disquisitions. The substance and diction of these, however, were not theirs but his own, and, of course, the gestures, which they had mechanically associated with certain characters, conveyed to them no notion of the real signification of those characters. Notwithstanding the radical and glaring defects of De l'Épée's method, which could have had no utility to those who followed it, the ostentatious display he made (which was of a nature particularly calculated to impose upon superficial observers) excited the astonishment and applause of a host of spectators; and, being seconded by the impulse of his religious zeal and beneficent character, it soon raised him to a high degree of reputation. His fame spread all over Europe, and his lectures and exhibitions attracted everywhere crowds of enthusiastic admirers. Some, however, saw through the delusion. At a public exhibition of the pupils of the Abbé Storek, who were taught according to this method at Vienna, Nicolai, an Academician of Berlin, proposed to the Abbé to require one of his pupils to describe in writing the action he was about to perform. The challenge being accepted, the Academician struck his breast with his hand, upon which the deaf and dumb boy wrote the words, "hand, breast." Nicolai withdrew satisfied with this proof of total failure. It was evident that, notwithstanding their apparent knowledge and their quickness in writing down any question together with its answer, both had been equally dictated by their master, in the same language of gesture, but without any corresponding ideas or the exertion of any intellectual faculty, except that of memory. They were utterly incapable of composing a single sentence of their own accord; and it was found, accordingly, that their spontaneous answers to questions were limited to the monosyllables yes and no, of which it is even doubtful whether they fully understood the meaning. The proper method by which the pupils' knowledge of the construction of language can be tested is by dictating the lesson in the sign language in the manner in which deaf mutes themselves use it, without any regard to logical or grammatical distinctions. Most pupils after a few months' instruction will be able to write down a very fair piece of composition if dictated by the method as employed by the Abbés de l'Épée and Storek, but without understanding its meaning. The following instance will at once explain the way in which the sign language is employed by the teachers, and used amongst the deaf and dumb themselves—

Let it be supposed that a girl had been seen by a deaf mute child to drop a cup of milk which she was carrying home. He would relate the incident in the following order of sign words. Saw-I-g-? walk-cup-milk-carry-home-drop. This mode of dictating is the only sure road to the acquisition of language by those who have nothing but the natural language of gesture and feature to assist them.

The value of the language of signs is well expressed by the principal of the Ohio Institution for the Deaf and Dumb, who says:—

"The use of good scaffolding must attend the erection of every building. A scaffolding in architecture so is the sign language in deaf mute education, and only tyros in architecture or education would dispense with either. The riper the experience the deeper the conviction comes of the necessity and usefulness of the sign language, and in its use we find the corner stone of all deaf mute institutions. The cultivation of it and its effective use is the only peculiar, although not the chief qualification of the teacher. He will teach written language by the sign, laying aside the latter as soon as the ready use of the former has been secured. It is not necessary to descend upon the beauty, the grace, or the power of the sign language. The mute has no other, and the teacher must use and improve it as best he may."

The first lesson in which the pupils are instructed on their entrance into school is the mode of visible communication known as the finger or manual alphabet. There are two kinds of this,—the *doubled-handed* alphabet, where the letters are expressed by the dispositions of the fingers of both hands, and the *single handed*, in which the letters are formed with the fingers of one hand. It is supposed that the former was derived from a finger-alphabet which appeared in a work by Dalgarno, and the latter is said to have been invented in Spain, and appears to have been published in a work by Bonet to which the Abbé de l'Épée was much indebted.

The Double-handed Alphabet, as in use in most of the schools for the deaf and dumb in England.

Talking with the fingers is an art easily acquired and retained, or recovered if lost, and it furnishes a ready substitute for pen or pencil; but it must not be forgotten by those familiar with it that the extent to which the deaf mute will be able to understand any communication will depend entirely upon the state of his education, or upon his knowledge of language. The deaf and dumb when

properly instructed converse with the utmost rapidity by this method; habit enables them to follow with the eye

The Single-handed Alphabet, as used in the American and Continental schools, and also in one or two English schools.

motions which to others would be too rapid for observation. They readily catch at the meaning of a word or question before it is half spelt.

Articulation.—Another very important branch of the education of the deaf and dumb is that system by which deaf mutes are taught to speak and to understand the speech of others by merely watching the motion of the vocal organs. This method is by no means novel, as it has long been practised in some of the schools in England, and the earliest attempts to teach the deaf and dumb to speak appear to have been as successful as those in modern times. We learn from the Venerable Bede's *Ecclesiastical History* (quoted by the Abbé Carton in his *Annual of the Deaf and Dumb and Blind*) that a deaf man was taught to pronounce words and sentences by John, bishop of Hagulstadt (Hexham), in the year 685, and from that time we meet with only isolated cases, till the latter part of the 18th century, when Samuel Heinicke established a school where this system formed the basis of instruction.

It would at first sight appear scarcely credible that a person, without the guidance of the sense of hearing, would be able, merely by watching the position and actions of the organs of the voice, to utter articulate sounds, with any tolerable perfection. Experience, however, has shown that this accomplishment, though laborious and tedious of acquisition, is not attended with extreme difficulty. Great patience, perseverance, and kindness are qualifications necessary on the part of the teacher to ensure success in ordinary cases, and the degree of success will greatly depend upon the number of children among whom the teacher has to divide his attention. A wide difference must ever be perceptible between the speech of the deaf and those who hear. This artificial speech is laborious and constrained. It frequently conveys the idea of pain as well as effort, and as it cannot be regulated by the ear of the speaker, it is often too loud, and generally monotonous, harsh, and discordant. It is often from this cause scarcely intelligible except to those who are accustomed to its tones. The

system of articulation and lip reading prevails in the German and other Continental schools, where this art has been cultivated with greater success than in England, which must be attributed to the adaptability of the German language to this peculiar mode of acquiring speech; the decision of this question, as far as it concerns any particular individual, must, however, depend in a great measure on peculiar circumstances, such as condition in life and future destination, &c. Children congenitally deaf, of good capacity, with a well-toned voice, can make surprising progress in the hands of private tutors; but the limited success which has attended this method of instruction with numbers has not induced teachers to introduce it generally into large institutions, but rather to restrict it to special cases. Most of the German teachers consider that articulation is necessary for the acquisition of thought, and can be successfully taught to the majority of the deaf and dumb; but most teachers of experience in England hold quite the opposite opinion, and teach it only to the semi-mute and semi-deaf. This subject continues to be much disputed, and the question, whether or not it should form a part of the course of the education of the deaf and dumb, and, if so, to what extent, is still keenly discussed. The American institutions have sent over to Europe from time to time some of their most distinguished instructors to investigate the methods carried on in the English and Continental schools. They made most minute examinations of the different systems, and were somewhat disappointed to find that the German system so-called did not possess such advantages over theirs, or the French system, as they had been led to expect. Mr Gallaudet, in his report to the board of directors of the Columbian Institution for the Deaf and Dumb, says:—"Nothing in my foreign investigations has led me to question the character of the foundation on which the system of instruction pursued in our American institutions is based. It is plainly evident, from what is seen in the articulating schools of Europe and from the candid opinions of the best instructors, that oral language cannot, in the fullest sense of the term, be mastered by a majority of deaf mutes." The following is the opinion of the Rev. George Day:—"As a regular part of a system of public instruction, its introduction into our institutions, I am persuaded, would be a serious misfortune." Mr Hawkins (for many years a teacher in the London school), who may be said, in this connection, to represent the consensus of English authorities, says:—"Scarcely more than one in thirty attains anything approaching success."

The experience of Dr Watson, for many years principal of the London Asylum, is decidedly in favour of its utility. In support of his opinion he states the following argument, which must doubtless be allowed to have some weight:—

"The more numerous are the means of observation, the more perfect will be the recollection, or, in other terms, the more frequent the recurrence of words and their corresponding ideas to the mind. Thus, persons who can hear, speak, read, and write retain a discourse much better, and have far greater facility in expressing themselves, than persons who possess only two of these faculties, that is, illiterate persons, who can hear and speak, but who cannot read or write. Now, as deaf and dumb persons educated without articulation can only have two of the means, viz., the third and the fourth, that is, the impressions made upon the eye by characters and the action of the hand in writing, can it be questioned that to render them an essential service by adding the actions of the organs of speech, a very powerful auxiliary, since by it words become, as it were, a part of ourselves, and more immediately affect us? In learning the pronunciation of letters, a very important operation is going on in the mind of a deaf person, namely, the association and understanding of the figures of written or printed character with certain movements or actions of the organs of speech. The very habit of regarding the one as the representative of the other paves the way for considering combinations of those actions or characters, as the sign of things or ideas—that is, significant

words, written or articulate. We who hear consider words chiefly as sound; the deaf who have learned to speak consider them rather as actions proceeding from themselves. And thus gives language to them a sort of tangible property, which is of vast importance both as respects its retention in the memory, and one of its most important uses, the excitation of ideas in their own minds. On this account the time, the labour, and attention, necessary to articulate speech by those who are dumb through want of hearing, would be well bestowed, even if their speech were not intelligible to others."

In America oral teaching is now receiving much attention. It has been introduced into several of the existing institutions, and two or three schools have been established in which the German system is exclusively carried out, and in order to facilitate the acquisition of articulate speech, the ingenious method called "Visible Speech," invented by Mr Melville Bell, has been introduced.¹ In England, also, there are several ardent advocates of the oral system.

Time of School Attendance.—After the foregoing sketch and criticism of the different methods which have been adopted for the education of the deaf and dumb, it is natural to inquire what general end in their education is proposed by teachers, and what principal aims in conformity with that end should be regarded. Obviously the fundamental object should be to qualify the pupils to hold ready communication with persons who, having the faculties of hearing and speech, employ the current language of the country for the purposes of mutual intercourse. They must above all things be taught the use of ordinary language, both as an instrument for expressing their own thoughts and for understanding those of others. This qualification, it is evident, is absolutely necessary to their becoming members of that community from which by nature they would have been excluded, and to which it is our chief aim to restore them.² Teachers are not agreed as to the age at which the deaf and dumb should commence their education with the greatest benefit, nor yet as to the term required for school attendance. It is the opinion of some that infant schools for the deaf and dumb would prove of immense advantage in compensating for the extra length of time requisite to acquire anything like a perfect knowledge of the English language, but others are strongly opposed to these for social, physical, and intellectual reasons,—socially, as it tends to alienate the children from their parents; physically, as being naturally of delicate constitutions they require the years of childhood to be invigorated, and so to be fitted to undergo the strain of a regular and systematic course of instruction; and intellectually, as it has been found by experience that children of an early age have not that power of comprehension or memory to enable them to advance with satisfaction. Doubtless, they would benefit somewhat by coming to a school for the deaf and dumb for a short time daily; but as the deaf-mute population is so scattered, very few would be able to avail themselves of such a privilege. The only available remedy would be their attendance at ordinary schools for a stated time daily, where they would be disciplined and taught—the girls to sew, knit, and write, and the boys to write and draw. By this suggestion it is not meant to affirm the possibility of educating deaf mutes along with hearing children. The plan has been tried but has not been successful. The constant observation of the deaf mutes of the superiority of others over them tends to dishearten and depress them, and as they are at

¹ Mr Bell has also invented an instrument called a Phonograph, which he says has been found useful for educational purposes, as was demonstrated by a young deaf and dumb pupil from the Boston institution.

² "Most institutions experience some difficulty in securing and then retaining able and efficient teachers, as the sphere of labour in the profession is so circumscribed and the salaries offered are far from being an equivalent remuneration for the sacrifice of brighter prospects and the depressing influence of the work."

with Dr Watson as principal. Its existence becoming more generally known, the number of candidates for admission increased so greatly beyond the means of accommodation that a larger and more commodious building was found to be absolutely necessary. An appeal for funds to erect such a building was made and liberally responded to, and an eligible plot of ground was taken in the Old Kent Road, London; and on the 11th of July 1807 the late duke of Gloucester laid the foundation stone of the new building. Since its foundation 1094 children have been admitted. In 1862 a branch was started at Margate, and after twelve years' experience the committee of management were influenced to erect a permanent building for the accommodation of 150 children. It was formally opened by the Prince of Wales on the 19th of July 1876, with Mr R. Elliott as head master. The asylum, with the branch at Margate, is supported by voluntary contributions, legacies, donations, and dividends from stock. The average income is about £12,000 a year. There are at present 317 pupils in attendance, who come from all parts of the kingdom. The ages of admission are $8\frac{1}{2}$ to $11\frac{1}{2}$, and the children are elected by votes of the subscribers; and, with a view to assist that class of the deaf and dumb whose friends are able to pay for their board, the committee receive children upon the payment of £25 per annum. Those children whose parents or guardians are unable to put them to some useful trade on leaving school are apprenticed by the charity. Since 1811 the number of children apprenticed has been 1515, and the total amount of premium £14,632, 16s.

Various institutions for similar objects have been formed on the Continent. The asylum for the deaf and dumb at Paris, which was formerly under the management of the Abbé Sicard, has for its object not only to enable the pupils to communicate their ideas and to form the understanding, but also to qualify them to earn their subsistence. On quitting the asylum they are all capable of following a trade or profession. Their apprenticeship begins on their first entering the institution, and is terminated when their education is finished.

Institutions, formed more or less upon the model of that at Paris, have been established in Portugal, Spain, Italy, Switzerland, Baden, Wurtemberg, Bavaria, Austria, Saxony, Hesse-Cassel, Nassau, Hanover, Brunswick, the Free Towns of Germany, Belgium, Holland, Denmark, Sweden, Russia, Poland, the United States of America, Canada, Mexico, and Bengal, to say nothing of those in Great Britain and France. The American annals of 1873 give us 35 American institutions for the education of the deaf and dumb, containing a total of 4253 pupils—namely, 2393 males and 1860 females, 378 of whom are semi-mutes. The latter number includes all the deaf who have acquired language through the ear. In Canada there are 4 institutions with 292 pupils, of whom 220 are males and 72 females. Out of this number 17 are semi-mutes. The first institution for the education of deaf mutes in America was opened on the 15th April 1817. The circumstances which led to its establishment are as follows:—

A deaf-mute little girl in the family of Dr Cogswell, an eminent physician in Hartford city, attracting some attention, it was soon afterwards found that there were other deaf mutes in the country. It was decided to send some one abroad to acquire the art of educating them; and to establish a school for this purpose funds were raised, and the Rev. F. H. Gallaudet, D.D., was selected for this work. He left the United States, May 15, 1816, to execute this mission intrusted to him. The Institution was incorporated by the Connecticut Legislature in May 1816, under the name of the Connecticut Asylum for the Education of the Deaf and Dumb.

Mr Gallaudet returned to America in August 22 of the same year, accompanied by Mr L. Clerc, a deaf-mute pupil of the Abbé Sicard. They immediately commenced collecting funds to start the school. The enterprise excited general interest, and individuals and churches

contributed liberally. The sum of \$12,000 was raised in the course of a few months, \$5600 having been obtained in Massachusetts, above \$2000 of which was collected in the city of Boston. After this school had been founded, the need of other schools was at once felt, and the New York Institution was opened in 1818, that in Pennsylvania in 1822, the one in Kentucky in 1823, Ohio school in 1829, and others followed till the number reached to 35, the last of which, a day school, was opened at Cleveland, Ohio, in 1871.

In America, and in almost every country in Europe except Great Britain and Ireland, the state successfully undertakes the instruction of the deaf and dumb. All the institutions are munificently supported by large annual appropriations from the local legislatures, the state regarding it as a primary duty that the deaf and dumb, the blind, &c., shall not be excluded from those educational privileges accorded to every member of the community.

In a spirit of enlightened liberality, highly creditable to the United States, the Government of that country adopts the deaf and dumb as "wards of the commonwealth," and in the most generous manner acquits itself of its obligation towards them. The following facts have been taken from the official reports of some American institutions:—

The number of pupils in the Indiana Institution in the year 1870 was 186; for these the State had granted a sum of 50,000 dollars, which is equal to £10,400, or £56 per annum for each pupil. A still further sum of 42,500 dollars, or nearly £9,000 sterling, was given for the erection of some additional buildings which the requirements of the Institution demanded. Every other State in the Union provides for its deaf-mute ward with similar generosity.

It is to be hoped that the day is not far distant when the deaf and dumb in Great Britain and Ireland may be congratulated on the inauguration by the legislature of a humane and beneficent policy on their behalf.

In many of the large towns where institutions are established, associations in aid of the deaf and dumb are springing up and carrying on most important and valuable work. Their first business is to seek out neglected children and to get them placed in some special school. Situations are procured for those on leaving school whose parents are unable to do anything for them, and the education commenced at the institutions is carried on by means of lectures; and as little benefit is to be got by attending the ordinary church services, meetings are held on Sundays, when suitable religious exercises are performed, portions of Scripture explained, and an address given by spelling with the assistance of such signs as may be found necessary. The missionaries connected with these associations call upon them at their homes, in this way making themselves familiar with their condition; the sick are visited and receive consolation; and the distressed, infirm, and aged are assisted. These associations, while rendering assistance to the deserving, endeavour to make them help themselves, and help only at the point where otherwise they would be lost; and it has been made a rule that when one loses his place through any fault of his own, he cannot claim the assistance of the association to find another for him. There seem to be few societies which have a greater claim on public sympathy, and that it deserves recognition is testified by the great good it is doing to this neglected and isolated class of persons, many of whom would otherwise have probably acquired habits of idleness and intemperance.

In the English census returns for 1871 we find that only 529 deaf mutes, out of a total of 11,518, of whom 51 were imbeciles and 26 blind as well as deaf and dumb, were inmates of workhouses in England and Wales. That small proportion affords evidence of the fact that by means of education the deaf and dumb may be transferred from the dependant and burdensome class into the self-supporting class of the community.

STATISTICS.

By the census of 1871, in Great Britain there are returned as deaf and dumb 19,236.

Table I shows the number of deaf and dumb persons in the United Kingdom in 1871, with the proportion which they bear to the whole population

Census, 1871	Number of Deaf and Dumb	Total Population.	Proportion to Population
England and Wales ..	11,518	22,712,266	1 in 1972
Scotland ..	2,087	3,360,018	1 in 1610
Ireland ..	5,554	5,402,759	1 in 975
Islands of the British Seas	77	144,638	1 in 1879
Total ..	19,236	31,619,681	1 in 1644

The above, compared with the returns of the census of 1861, with an increase of population of 2½ millions during that decennial period, will show an absolute decrease of 1075 deaf mutes, viz., 718 persons in England and Wales, 248 in Scotland, 99 in Ireland, and 10 in the islands of the British seas.

Census, 1861	Number of Deaf and Dumb	Total Population	Proportion to Population
England and Wales..	12,236	20,066,224	1 in 1640
Scotland ..	2,345	3,062,294	1 in 1311
Ireland ..	5,633	5,798,967	1 in 1026
Islands of the British Seas	87	143,447	1 in 1649
Total ..	20,311	29,070,932	1 in 1432

These figures afford an indication that causes are at work which are diminishing the extent of deaf-muteism in the country, such as direct sanitary improvements, general attention to the laws of health, and more skilful treatment of the diseases which result in deafness. Of the 11,518 deaf mutes in England and Wales in 1871 (including those described as dumb) 6202 are males and 5256 are females. In Scotland, out of the 2087 deaf mutes, 1133 are males and 954 females, of whom 1016 were ascertained to have been so from birth, while 1071 became so in after life from various causes. The number of deaf and dumb persons in Ireland is 5554, viz., in Leinster, 1818, Munster, 1590, Connanght, 882, and Ulster, 1764.

The instances of persons in the melancholy condition of being deaf and dumb and blind are more numerous than might be supposed, for the congenitally deaf are in a measure pre-disposed to the organic defect which results in blindness. No less than 111 persons were returned as deaf and dumb and blind, of these 20 were in special asylums and 26 in workhouses. In 1861 only 30 persons were described as blind and deaf and dumb.

As dumbness can only co-exist with deafness from birth or from early life, the number of deaf and dumb, unlike that of the blind, does not increase with age, but is highest immediately after the age when the epidemic diseases of children have been passed through.

Table II shows concisely the locality, the date of establishment, and approximately the number of pupils in each of the institutions in Great Britain and Ireland

Locality	Date of establishment.	No. of Pupils.
{London ..	1792	317

(A. LA)

DEAFNESS. See EAR.

DEÁK, FRANZ (1803-1876), an Hungarian statesman, was born on October 17, 1803, at Kohida, in the comitat of Szalad. He sprang from an old noble family, of which he was the last descendant. Having studied law at the academy of Raab, he practised as an advocate in Szalad, and soon became a prominent figure at the meetings of the comitat. He represented Szalad in the Diet which met at Presburg in 1832 and lasted till 1836. By his earnestness and practical sagacity he made so deep an impression that he was in a short time recognized as leader of the opposition. The object of his policy was, on the one hand, to resist the encroachments of the central Government at Vienna on the rights of his country, and, on the other, to remove abuses which then made Hungary one of the most backward nations in Europe. He again sat for Szalad in the Diet of 1839-40, and by skilful management effected a temporary reconciliation between the Imperial Government and the Reform party, of which he was the head. He gave deep offence, however, by the vigour with which he denounced the exemption of Hungarian nobles from taxation, as well as other injurious survivals of the Middle Ages; and when elected in 1843 he received such definite instructions from the constituency to vote in a reactionary sense that he declined to accept his seat. At a second election the Liberals exerted themselves so energetically that he was again appointed; but, on the ground that violence had been used in connection with his candidature, he once more refused to enter the Diet. For some years he lived as a private citizen; but he was everywhere regarded as the most influential Hungarian politician, and his party took no important step without consulting him. A project for a penal code which he drew up about this time was admitted in Germany, France, and England to be one of the most enlightened ever conceived. The excitement of 1843 caused the first symptoms of the disease of the heart of which he ultimately died; and during the rest of his life he always suffered more or less from ill health. On this account he could not enter the Diet of 1847, but next year, when revolutionary forces threatened to break up the empire, he was persuaded to take a seat vacated for him by one of the members for Szalad.

The emperor, alarmed by the dangers which surrounded him on every side, conceded in a number of measures, afterwards known as "the laws of 1848," every important demand Deák had ever made. The first independent Hungarian Cabinet, with Count Batthyány as president, was formed, and the ministry of justice was intrusted to Deák. In this office, during the few months he held it, he worked indefatigably; and he intended completely to reorganize legal administration. His plans, however, were

disturbed by the agitation of which Kossuth was the centre, and which aimed at changes of a more extreme character than he approved. He desired to maintain the relations of Austria and Hungary, and exercised his whole influence in favour of a good understanding between the two countries. Events decided against him, for Kossuth rose to power and began the war in the course of which the Hapsburg dynasty was formally deposed. Deák resigned his portfolio, and appeared in connection with the subsequent struggle only as one of the deputation which, on the approach of the Austrian army to Buda-Pesth, went to negotiate with Prince Windischgrätz. When the war was over, Deák was offered the post of *Judex Curiae*; but he insisted that the laws of 1848 were still in force, and would have nothing to do with any system of government in which they were ignored. On the other hand, he discountenanced violent proposals, urging that the legal rights of the land could be secured only by legal means.

Hungary suffered deeply from the reaction which followed the revolutionary period, and it was clear that she only awaited a favourable opportunity to throw off the imperial yoke. The disasters sustained by Austria in the Italian war of 1859 suggested to the emperor the necessity of a change of policy, and the result was that in 1861 the Diet again met. This time Deák appeared as member for Pesth, which henceforth returned him at every election till his death. The Moderate party rallied round him, and after much discussion the address to the emperor drawn up by him was adopted. In this the Diet took its stand on the laws of 1848, and demanded the appointment of a Hungarian ministry; but at Vienna they were not prepared to give way so far. The imperial rescript was very hostile in tone, and the Diet was speedily dissolved. In 1865 fresh negotiations were begun, and they were powerfully promoted by a series of letters in the *Pesti Napló*, setting forth Deák's ideas as to the proper bases of reconciliation. Towards the end of 1865 the Diet was opened by the emperor in person. About six months afterwards it was hastily closed because of the approaching war between Austria and Prussia; but it reassembled on November 19, 1866, when Austria had been utterly defeated and seemed on the brink of ruin. The Radical party wished to take advantage of the general confusion by exacting terms to which the Austrian Government would never before have consented; but Deák maintained his former position, desiring no more than that the system which he considered the only legal one should be forced. His influence over the Diet and the nation prevailed; and he had the satisfaction of seeing Count Andrássy appointed president of an Hungarian cabinet and the emperor and empress crowned as king and queen of Hungary. The establishment of the dual system, which enabled the Austro-Hungarian monarchy to enter upon a new career after terrible humiliations and losses, was due to the efforts of Deák more than to any other cause, and the fact was gratefully acknowledged both by the mass of his countrymen and by the emperor.

For some years the Deák party continued the most powerful in the Diet; but the state of his health rendered it impossible for him to do much more than deliver an occasional speech on subjects of unusual interest. His last speech, in the summer of 1873, was on the relations of church and state; and he proclaimed himself in favour of the American system—"a free church in a free state." Before his death his party lost its hold over the nation, and in 1875 Tisza, a man of more advanced opinions, was called to the head of the Government. Deák died on January 29, 1876, at Buda-Pesth, after a long and painful illness. His death was regarded as a national calamity, and he was buried at the cost of the state amid manifestations of universal grief.

Hungary has produced no other statesman of equal distinction. He approached closely to the type which is supposed to be peculiarly English, holding fast vital principles, but always ready to accede to a compromise on matters of secondary moment. Intensely opposed to revolution, he was absolutely fearless when sure that he was standing on lawful ground, and pursued the political ideal he had formed with a persistence which has been rarely equalled. In youth his style as an orator was passionate and florid; but he ultimately became calm and deliberate, carrying conviction by command of facts, logical arrangement of ideas, and lucid statement. At all periods of his career he conveyed the impression of absolute sincerity and devotion to high and unselfish aims. He was of a genial disposition, remarkably fond of children, and with a gift of ready humour which made him as great a favourite in society as in parliament. (J. St.)

DEAL, a municipal and parliamentary borough and market town of England, in the county of Kent, eight miles N.N.E. of Dover and five miles by rail S.E. of Sandwich. It consists of three divisions:—Lower Deal, which is the most important, on the coast; Middle Deal; and, about a mile inland, Upper Deal. Though largely frequented as a sea-bathing place, the town derives its importance mainly from its vicinity to the Downs, a fine anchorage about eight miles long and six miles wide between the shore and the Goodwin Sands, in which large fleets of wind-bound vessels may lie in safety. The trade consequently consists largely in the supply of provisions and naval stores; though boat-building and a few other industries are carried on. The Deal pilots, limited by statute to the number of 56, are famous for their skill and daring. Among the public buildings in the town the most remarkable are St Leonard's Church in Upper Deal, which dates from the Norman period; the Baptist chapel in Lower Deal, founded by Captain Taverner, governor of Deal Castle, in 1663; the Deal and Walmer Institute, established in 1864, the military and naval hospital; and the barracks, which date from 1795. The site of the old navy yard is now occupied by villas; and the esplanade has been improved by the construction of a promenade pier. At the south end of the town is Deal Castle, erected by Henry VIII.; and about a mile to the east is Sandown Castle, which owes its origin to the same monarch, and is of interest as the prison in which Colonel Hutchinson died in 1664. Walmer Castle, the official residence of the warden of the Cinque-Ports, is about a mile to the south. It has become intimately associated with the memory of the duke of Wellington, who died within its walls in 1852. Deal was possibly the site of a Roman station, but it has not received any definite identification. In the 13th century it was regarded as a subordinate member of the Cinque-Port guild; but even as late as the time of Henry VIII. it was still but a small village. Perkin Warbeck landed at this point in 1495. The castle was vainly besieged by the royalists in 1648, and in 1652 the Downs were the scene of Blake's victory over Van Tromp. Mrs Elizabeth Carter was a native of Deal. The population of the borough, which unites with Sandwich and Walmer in sending one member to Parliament, was, in 1871, 8009. The area is 1124 acres.

DEAN, Latin *decanus*, is derived from the Greek *δέκα*, ten; and whether the term was first used among the secular clergy to signify the priest who had a charge of inspection and superintendence over ten parishes, or among the regular clergy to signify the monk who in a monastery had authority over ten other monks, appears doubtful. "Decurius" may be found in early writers used to signify the same thing as "decanus," which shows that the word and the idea signified by it were originally borrowed from the old Roman military system.

The earliest mention which occurs of an "archipresbyter" seems to be in the 4th epistle of St Jerome to Rusticus, in which he says that a cathedral church should possess one bishop, one archipresbyter, and one archdeacon. Liberatus also (*Breviar. c. xiv*) speaks of the office of archipresbyter in a manner which, as Bingham says, enables one to understand what the nature of his duties and position was. And he thinks that those are right who hold that the archipresbyters were the same as the deans of our cathedral churches. Stillingfleet (*Irenic. part ii. c. 7*) says of the archipresbyters that "the memory of them is preserved still in cathedral churches, in the chapters there, where the dean was nothing else but the archipresbyter; and both dean and prebendaries were to be assistant to the bishop in the regulating the church affairs belonging to the city, while the churches were contained therein." Bingham, however, following Liberatus, describes the office of the archipresbyter to have been next to that of the bishop, the head of the presbyteral college, and the functions to have consisted in administering all matters pertaining to the church in the absence of the bishop. But this does not describe accurately the office of dean in an English cathedral church. The dean is indeed second to the bishop in rank and dignity, and he is the head of the presbyteral college or chapter; but his functions in no wise consist in administering any affairs in the absence of the bishop. There may be some matters connected with the ordering of the internal arrangements of our cathedral churches, respecting which it may be considered a doubtful point whether the authority of the bishop or that of the dean is supreme. But the consideration of any such question leads at once to the due theoretical distinction between the two. With regard to matters spiritual, properly and strictly so called, the bishop is supreme in the cathedral as far as—and no farther than—he is supreme in his diocese generally. With regard to matters material and temporal, as concerning the fabric of the cathedral, the arrangement and conduct of the services, and the management of the property of the chapter, &c., the dean (not excluding the due authority of the other members of the chapter, but speaking with reference to the bishop) is supreme. And the cases in which a doubt might arise on the point are those in which the material arrangements of the fabric or of the services may be thought to involve doctrinal considerations.

The Roman Catholic writers on the subject say that there are two sorts of deans in the church—the deans of cathedral churches, and the rural deans—as has continued to be the case in the English Church. And the probability would seem to be that the former were the successors and representatives of the monastic decurions, the latter of the inspectors of "ten" parishes in the primitive secular church. It is thought by some that the rural dean is the lineal successor of the *chorepiscopus*, who in the early church was the assistant of the bishop, discharging most, if not all, episcopal functions in the rural districts of the diocese. But upon the whole the probability is otherwise. Beveridge, Cave, Bingham, and Basnage all hold that the *chorepiscopus* were true bishops, though Romanist theologians for the most part have maintained that they were simple priests. But if the *chorepiscopus* has any representative in the church of the present day, it seems more likely that the archdeacon is such rather than the dean.

The ordinary use of the term dean, as regards secular bodies of persons, would lead to the belief that the oldest member of a chapter had, as a matter of right, or at least of usage, become the dean thereof. But Bingham (*lib. ii. ch. 18*) very conclusively shows that such was at no time the case, as is also further indicated by the maxim to the effect that the dean must be selected from the body of the

chapter—"Unus de gremio tantum potest eligi et promoveri ad decanatus dignitatem." The duties of the dean in a Roman Catholic cathedral are to preside over the chapter, to declare the decisions to which the chapter may have in its debates arrived by plurality of voices, to exercise inspection over the choir, over the conduct of the capitular body, and over the discipline and regulations of the church; and to celebrate divine service on occasion of the greater festivals of the church in the absence, or inability, of the bishop. With the exception of the last clause the same statement may be made as to the duties and functions of the deans of our cathedral churches.

Deans had also a place in the judicial system of the Lombard kings in the 8th, 9th, and 10th centuries. But the office indicated by that term, so used, seems to have been a very subordinate one; and the name was in all probability adopted with immediate reference to the etymological meaning of the word,—a person having authority over ten (in this case apparently) families. Muratori, in his *Italian Antiquities*, speaks of the resemblance between the *saltari* or *syliani* and the *decani*, and shows that the former had authority in the rural districts, and the latter in towns, or at least in places where the population was sufficiently close for them to have authority over ten families. Nevertheless, a document cited by Muratori from the archives of the canons of Modena, and dated in the year 813, recites the names of several "deaneries" (*decania*), and thus shows that the authority of the dean extended over a certain circumscription of territory.

In the case of the "dean of the sacred college," the connection between the application of the term and the etymology of it is not so evident as in the foregoing instances of its use; nor is it by any means clear how and when the idea of seniority was first attached to the word. This office is held by the oldest cardinal—*i.e.*, he who has been longest in the enjoyment of the purple, not he who is oldest in years—who is usually, but not necessarily or always, the bishop of Ostia and Velletri. Perhaps the use of the word "dean," as signifying simply the eldest member of any corporation or body of men, may have been first adopted from its application to that high dignitary. The dean of the sacred college is in the ecclesiastical hierarchy second to the Pope alone. His privileges and special functions are very many; a compendious account of the principal of them may be found in the work of Moroni, vol. xix. p. 168.

There are four sorts of deans of whom the law of England takes notice. 1. The dean and chapter are a council subordinate to the bishop, assistant to him in matters spiritual relating to religion, and in matters temporal relating to the temporalities of the bishopric. The dean and chapter are a corporation, and the dean himself is a corporation sole. Deans are said to be either of the old or of the new foundation—the latter being those created and regulated after the dissolution of the monasteries by Henry VIII. The deans of the old foundation before 3 and 4 Vict. c. 113 were elected by the chapter on the king's *conseil d'élire*; and the deans of the new foundation (and, since the Act, of the old foundation also) are appointed by the king's letters patent. It was at one time held that a layman might be dean; but by 13 and 14 Charles II. c. 4, priest's orders are a necessary qualification. Deaneries are sinecures in the old sense, *i.e.*, they are without cure of souls. The chapter formerly consisted of canons and prebendaries, the dean being the head and an integral part of the corporation. By 3 and 4 Vict. c. 113, it is enacted that "all the members of the chapter except the dean, in every collegiate and cathedral church in England, and in the cathedral churches of St David and Llandaff, shall be styled canons." By the same Act the dean is required to

be-in residence eight months, and the canons three months, in every year. The bishop is visitor of the dean and chapter. 2. The dean of peenbars "hath no chapter, yet is presentative, and hath cure of souls; he hath a *peculiar*, and is not subject to the visitation of the bishop." 3. The third dean "hath no cure of souls, but hath a court and a *peculiar*, in which he holdeth plea and jurisdiction of all such ecclesiastical matters as come within his peculiar. Such is the Dean of the Arches, who is the judge of the court of the arches, the chief court and consistory of the archbishop of Canterbury, so called of Bow Church, where this court was ever wont to be held." The parish of Bow and twelve others are within the peculiar jurisdiction of the archbishop in spiritual causes, and exempted out of the bishop of London's jurisdiction. 4. Rural deans are clergymen whose duty is described as being "to execute the bishop's processses and to inspect the lives and manners of the clergy and people within their jurisdiction" (see Phillimore's *Ecclesiastical Law*).

In the colleges of the English universities one of the fellows usually holds the office of "dean," and is specially charged with the discipline, as distinguished from the teaching functions of the tutors.

DEBENTURE, a deed by which certain property is charged with the repayment of money lent at a fixed interest. It is commonly adopted by companies of a public nature as a means of raising money for carrying on their undertakings. The creation of debenture stock in such companies is regulated in England by the Companies Clauses Act, 1863, part iii, which makes debenture stock a prior charge on the undertaking, and gives the interest thereon priority of payment over all dividends or interest on any shares or stock of the company, whether ordinary or preference or guaranteed. Payment of arrears may be enforced by appointment of a receiver, or (in Scotland) of a judicial factor.

DEBRECZYN, or **DEBRETZN**, a royal free city of Hungary, the chief town of the comitat of Hadju, and one of the largest in the kingdom, is situated in the midst of a slightly elevated sandy plain 114 miles east of Pesth, with which it is connected by rail. It is a meanly-built, straggling town, with irregular suburbs stretching out into the plain; its wide roadways are only paved with wood down the centre and along the sides; its houses are with few exceptions only one story high, and the courtyards or gardens with which they are usually furnished give the whole place the appearance of an overgrown village, in spite of the number of its public buildings. The most prominent of these is the principal Protestant church, which ranks as the largest in the country, but has no great architectural pretensions. In its immediate neighbourhood is the Protestant Collegium, a large and flourishing institution founded in 1792, and possessed of an extensive library. The town-house, the Franciscan church, the Piarist monastery and college, and the theatre are worthy of mention; there are also hospitals, two gymnasiums, and an agricultural academy. The industries of the town are pretty various, but none of them are of importance enough to give it the character of a manufacturing centre. Its tobacco-pipes, of the genuine national style, its sausages, and its soap are widely known; and the first of the three are imported to England and France. Flour and beet-root sugar are also manufactured. Every three months the neighbouring plain is covered with the booths and bustle of a great fair; but since the opening of the railway there is hardly so extensive a concourse as before. Between 300 and 400 square miles of territory belong to the municipality, which derives a large annual revenue from the woods, pastures, &c. The inhabitants are, with very few exceptions, of Magyar origin and Calvinistic creed, and are in bad

repute for their alleged selfishness and inhospitality. The town is of considerable antiquity, but owes its development to the refugees who fled from the villages plundered by the Turks in the 15th century. In 1552 it adopted the Protestant faith, and it had to suffer in consequence, especially when it was captured in 1686 by the imperial forces. In 1693 it was made a royal free city. In 1848-9 it formed a refuge for the National Government and Legislature when Buda-Pesth fell into the hands of the Austrians; and it was in the great Calvinist church that Kossuth read the proclamation that declared the house of Hapsburg to have forfeited the crown of Stephen. On the 3d of July the town was captured by the Russians. Population in 1869, 46,111.

DEBT is a sum certain due by one person to another. It may be created by contract, by statute, or by judgment. By the Judicature Act, 1873, any absolute assignment of any debt or other legal chose in action, of which express notice in writing shall have been given to the debtor, trustee, or other person from whom the assignor would have been entitled to receive or claim such debt, shall be effectual in law. If the debtor receives notice that such assignment is disputed by the assignor, or any one claiming under him, he may call upon the parties to interplead concerning the same, or he may pay the money into court in conformity with the Acts for the Relief of Trustees. Order xlv. of the Rules of Court under the same Act contains the provisions under which the debts due to a person against whom a judgment has passed for the payment of money may be attached by the judgment creditor. See **BANKRUPTCY**.

DECALOGUE (in patristic Greek, ἡ δεκάλογος, *sc.*, βιβλος or νομοθεσία) is another name for the *ten commandments*, in Hebrew the *ten words* (Deut. iv. 13, x. 4; Exod. xxxiv. 28), written on the two tables of stone, the so-called *tables of the revelation* (E. V., tables of testimony—Ex. xxxiv. 29, comp. ch. xxv. 21), or *tables of the covenant* (Deut. ix. 9). In Deuteronomy the inscription on these tables, which is briefly called *the covenant* (iv. 13), is expressly identified with the words spoken by Jehovah out of the midst of the fire at Mount Sinai in the ears of the whole people on the "day of the assembly," and rehearsed in ch. v. 6-21. In the narrative of Exodus the relation of the "ten words" of ch. xxxiv. to the words spoken from Sinai, ch. xx. 2-17, is not so clearly indicated—a circumstance which has given rise to speculations as to the possible existence of a second decalogue. Before entering on this question, however, we must examine the decalogue as usually understood and embodied in the parallel passages in Exod. xx. and Deut. v.

1. *The variations in the parallel texts*, so far as they are important for the criticism of the decalogue, are mainly two. (a) The reason assigned for the institution of the Sabbath in Exodus is drawn from the creation, and agrees with Gen. ii. 3. In Deuteronomy the command is based on the duty of humanity to servants and the memory of Egyptian bondage. (b) In the tenth commandment, as given in Exodus, "house" means house and household, including all the particulars which are enumerated in ver. 17. In Deuteronomy, "Thou shalt not covet thy neighbour's wife" comes first, and "house" following in association with field is to be taken in the literal restricted sense.

2. *The construction of the Hebrew text* of the second commandment is disputed, but the most natural sense seems to be, "Thou shalt not make unto thee a graven image, [and] to no visible shape in heaven, &c., shalt thou bow down, &c." The third commandment might be better rendered, "Thou shalt not utter the name of the Lord thy God vainly."

3. *Divisions of the Decalogue*.—The division current in

England and Scotland, and generally among the Reformed (Calvinistic) churches and in the Greek Church, is known as the Philonic division (Philo *de Decalogo*, § 12). It is sometimes called by the name of Origen, who adopts it in his *Homilies on Exodus*. On this scheme the preface, Exod. xx. 2, has been usually taken as part of the first commandment. The Church of Rome and the Lutherans adopt the Augustinian division (Aug., *Quæst. super Exod.*, lxxi.), combining into one the first and second commandments of Philo, and splitting his tenth commandment into two. To gain a clear distinction between the ninth and tenth commandments on this scheme it has usually been felt to be necessary to follow the Deuteronomic text, and make the ninth commandment, Thou shalt not covet thy neighbour's wife.¹ As scarcely any scholar will now claim priority for the text of Deuteronomy, this division may be viewed as exploded. But there is a third scheme (the Talmudic) still current among the Jews, and not unknown to early Christian writers, which is still a rival of the Philonic view. The preface, Exod. xx. 2, is taken as the first word, and the second embraces verses 3-6. Among recent Christian writers who have adopted this view are Knobel (in his *Com. on Exodus*) and Kuenen (*Godsdienst van Israël*, i. 278 ff.). The decision between Philo and the Talmud must turn on two questions. Can we take the preface as a separate word? And can we regard the prohibition of polytheism and the prohibition of idolatry as one commandment? Now, though the Hebrew certainly speaks of ten 'words,' not of ten 'precepts,' it is most unlikely that the first word can be different in character from those that follow. But the statement "I am the Lord thy God," is either no precept at all, or only enjoins by implication what is expressly commanded in the words "Thou shalt have no other gods before me." Thus to take the preface as a distinct word is not reasonable unless there are cogent grounds for uniting the commandments against polytheism and idolatry. But that is far from being the case. The first precept of the Philonic scheme enjoins monolatry, the second expresses God's spiritual and transcendental nature. Accordingly Kuenen does not deny that the prohibition of images contains an element additional to the precept of monolatry, but, following De Goeje, regards the words from "thou shalt not make unto thyself" down to "the waters under the earth" as a later insertion in the original decalogue. Unless this can be made out—of which below—the Philonic scheme is clearly best, and as such it is now accepted by most scholars.

How were the ten words disposed on the two tables? The natural arrangement (which is assumed by Philo and Josephus) would be five and five. And this, as Philo recognized, is a division appropriate to the sense of the precepts; for antiquity did not look on piety towards parents as a mere precept of probity, part of one's duty towards one's neighbour. The authority of parents and rulers is viewed in the Old Testament as a delegated divine authority, and the violation of it is akin to blasphemy (comp. Ex. xxi. 17, Lev. xx. 9, with Lev. xxiv. 15, 16, and note the formula of treason, 1 Kings xxi. 13).

We have thus five precepts of piety on the first table, and five of probity on the second, an arrangement which is accepted by the best recent writers. But the current view of the Western Church since Augustine has been that the precept to honour parents heads the second table. The only argument of weight in favour of this view is that it makes the amount of writing on the two tables less unequal, while we know that the second table as well as

the first was written on both sides (Ex. xxxii. 15). But we shall presently see that there may be another way out of this difficulty.

4. *Critical questions*—That the decalogue not only contains Mosaic ideas; but is as old as Moses in its form as a system of "ten words," is admitted by critics of almost every school.² But it is much disputed what the original compass of the decalogue was. Did the whole text of Exod. xx. 2-17 stand on the tables of stone? The answer to this question must start from the reason annexed to the fourth commandment, which is different in Deuteronomy. But the express words "and he added no more," in Deut. v. 22, show that there is no conscious omission by the Deuteronomic speaker of part of the original decalogue, which cannot therefore have included the reason annexed in Exodus. On the other hand the reason annexed in Deuteronomy is rather a parenthetic addition than an original element dropped in Exodus. Thus the original fourth commandment was simply "Remember the Sabbath day to keep it holy."³ When this is granted it must appear not improbable that the elucidations of other commandments may not have stood on the tables. Thus in the second commandment, "Thou shalt not bow down to any visible form," &c., is a sort of explanatory addition to the precept "Thou shalt not make unto thee a graven image." And so the promise attached to the fifth commandment was probably not on the tables, and the tenth commandment may have simply been, "Thou shalt not covet thy neighbour's house," which includes all that is expressed in the following clauses. Such a view gets over the difficulty arising from the unequal length of the two halves of the decalogue. The elucidations (unless in the case of the fourth commandment) may very well be as old as Moses (comp. Ewald, *Geschichte*, ii. 229). It is quite another question whether there is any idea in the decalogue which cannot be as old as Moses. It is urged by many critics that Moses cannot have prohibited the worship of Jehovah by images, for the subsequent history shows us a descendant of Moses as priest in the idolatrous sanctuary of Dan. There were teraphim in David's house, and the worship of Jehovah under the image of a calf was the state religion of the kingdom of Ephraim. It is argued from these facts that image worship went on unchallenged, and that this would not have been possible had Moses forbidden it. This argument does not appear to have all the force that Kuenen and others attach to it, for it must be remembered how large a section of Christendom, in times much more advanced than those of the Old Testament, has accepted the decalogue and yet has worshipped images. And on the other side we have the much more cogent arguments that the number of ten words, which no one doubts to be primitive, cannot be naturally made out if the law against images is dropped, and that the existence of this law is necessary to explain the fact that the unquestionably Mosaic sanctuary of the ark, which is just the sanctuary of the revelation of the ten words, embodies the principle of the worship of Jehovah without images in a distinct and practical form. It may be added that the prohibition of images of hewn stone, which is the primitive sense of the word "graven-image," can hardly be less ancient than the conception that the stones of an altar were defiled by the touch of the chisel (Exod. xx. 24). And this is a conception which cannot be viewed as a later refinement on Mosaic ideas.

5. *The Decalogue of Exodus xxxiv.*—In the book of Exodus the words written on the tables of stone are nowhere expressly identified with the ten commandments of

¹ So, for example, Augustine, *l. c.* Thomas, *Summa (Prima Secundæ, qu. c. art. 4)*, and recently Sonntag and Kurtz. Purely arbitrary is the idea of Lutheran writers (Gerhard, *Loc. xiii.* § 46) that the ninth commandment forbids concupiscentia actualis, the tenth conc. originalis.

² Exceptions to this consensus are Vatke (*Biblische Theologie*, p. 202) and Nöldeke (*Untersuchungen*, p. 51).

³ It is generally assumed that the addition in Exodus is from the hand that wrote Gen. i.-ii. 4.

chap. xx. In xxv. 16 xxxi. 18, xxxii. 15, we simply read of "the revelation" inscribed on the tables, and it seems to be assumed that the contents of this revelation must be already known to the reader. The expression "ten words" first occurs in xxxiv. 28, in a passage which relates the restoration of the tables after they had been broken. But these "ten words" are called "the words of the covenant," and so can hardly be different from the words mentioned in the preceding verse as those in accordance wherewith the covenant was made with Israel. And again, the words of verse 27 are necessarily the commandments which immediately precede in verses 12-26. Accordingly many recent critics, following Hitzig,¹ who seems to have formed his view without reference to a previous suggestion of Goethe's, have sought to show that Exod. xxxiv. 12-26 contains just ten precepts forming a second decalogue. In point of detail it is disputed whether the narrator of Exod. xxxiv. regards this decalogue as precisely identical with that which stood on the first tables (which seems to follow from xxxiv. 1) or as a modification of the original words (so Ewald). It does not seem possible to deny the connection of verses 27, 28 with one another and with the previous context as the text now stands. Hengstenberg (*Beiträge*, ii. 387 ff.) and Bertheau (*Sieben Gruppen Mosaischer Gesetze*, p. 97) seek to distinguish the words of verse 28, as written by God himself, from those which, in verse 27, Moses is commanded to write. But no such distinction lies in the text, and it is not probable that the narrator felt any contradiction between God's promise to write the words in verse 1 and the use of human instrumentality as implied in verse 28. On the other hand, the hypothesis of a second decalogue has serious if not insuperable difficulties. The number of ten precepts in Exod. xxxiv. is by no means clearly made out, and the individual precepts are variously assigned by different critics; while the most recent supporter of the theory admits that the original number of ten is now concealed by additions.² This supposed decalogue contains no precepts of social morality, but forms a sort of unsystematic abstract of the oldest laws about points of religious observance. If such a system of precepts was ever viewed as the basis of the covenant with Israel, it must belong to a far earlier stage of religious development than that of Exod. xx. This is recognized by Wellhausen, who says that our decalogue stands to that of Exod. xxxiv. as Amos stood to his contemporaries, whose whole religion lay in the observance of sacred feasts. But the idea that the ethical teaching of the prophets had no basis in the original document of the Mosaic covenant is so revolutionary that few will venture to accept "Goethe's decalogue" with such inferences. The difficulty is presumably due to the interweaving of several distinct narratives, which perplexes the sequence of many parts of Exodus. It is more probable that xxxiv. 10-27—a summary of the religious precepts of the Mosaic covenant—originally stood in a different connection than that there ever were two opinions as to what stood on the tables.

6. *The Decalogue in Christian Theology.*—Following the New Testament, in which the "commandments" summed up in the law of love are identified with the precepts of the decalogue (Mark x. 19; Rom. xiii. 9, cf. Mark xii. 28 ff.), the ancient church emphasized the permanent obligation of the ten commandments as a summary of *natural* in contradistinction to *ceremonial* precepts, though the observance of the Sabbath was to be taken in a spiritual sense (Augustine, *De Spiritu et Litera*, xiv.; Jerome, *De Celebratione Pasche*). The mediæval theologians followed in the same line, recognizing all the pre-

cepts of the decalogue as moral precepts *de lege naturæ*, though the law of the Sabbath is not of the law of nature, in so far as it prescribes a determinate day of rest (Thomas, *Summa*, I^{na} II^{ae}, qu. c. art. 3; Duns, *Super Sententias*, lib. iii. dist. 37). The most important mediæval exposition of the decalogue is that of Nicolaus de Lyra; and the 15th century, in which the decalogue acquired special importance in the confessional, was prolific in treatises on the subject (Antoninus of Florence, Gerson, &c.).

Important theological controversies on the decalogue began with the Reformation. The question between the Lutheran (Augustinian) and Reformed (Philonic) division of the ten commandments was mixed up with controversy as to the legitimacy of sacred images not designed to be worshipped. The Reformed theologians took the stricter view. The identity of the decalogue with the eternal law of nature was maintained in both churches, but it was an open question whether the decalogue, as such (that is, as a law given by Moses to the Israelites), is of perpetual obligation. The Socinians, on the other hand, regarded the decalogue as abrogated by the more perfect law of Christ, and this view, especially in the shape that the decalogue is a civil and not a moral law (J. D. Michaelis), was the current one in the period of rationalism in last century. The distinction of a permanent and a transitory element in the law of the Sabbath is found, not only in Luther and Melancthon, but in Calvin and other theologians of the Reformed church. The main controversy which arose on the basis of this distinction was whether the prescription of one day in seven is of permanent obligation. It was admitted that such obligation must be not natural but positive; but it was argued by the stricter Calvinistic divines that the proportion of one in seven is agreeable to nature, based on the order of creation in six days, and in no way specially connected with anything Jewish. Hence it was regarded as a *universal positive* law of God. But those who maintained the opposite view were not excluded from the number of the orthodox. The laxer conception found a place in the Cœcilian school.

Literature.—Geffcken, *Ueber die verschiedenen Einteilungen des Dekalog's und den Einfluss derselben auf den Cultus*, Ewald's *History of Israel*, vol. u.; Schultz's and especially Oehler's *Old Testament Theology*, Oehler's article "Dekalog" in Herzog's *Encyclopædie*; commentaries on Exodus, especially that of Knobel in German, and in English of Kalisch, Kuenen's *Godsdienst van Israel*, Hldst. v. Kurtz, *Geschichte des Alten Bundes*, Bd. ii., other literature cited by Oehler and by Koehler, *Biblische Geschichte*, i. 287. For guidance in the theological controversies about the Decalogue the student may consult Walch and Baumgarten. (W. R. S.)

DECAMPS, ALEXANDRE GABRIEL (1803-1860), one of the foremost painters of the modern French school, was born in Paris on the 3d March 1803. He received his artistic training from Abel de Pujol, but set himself free at an early period of his career from academic trammels. He asserted his originality in his choice of subjects as well as in his style of treatment. In his youth he travelled in the East, and reproduced Oriental life and scenery with a bold fidelity to nature that made his works the puzzle of conventional critics. His powers, however, soon came to be recognized, and he was ranked along with Delacroix and Vernet as one of the leaders of the French school. At the Paris Exhibition of 1855 he received the grand or council medal. Most of his life was passed in the neighbourhood of Paris. He was passionately fond of animals, especially dogs, and indulged in all kinds of field sports. He died on the 22d August 1860 in consequence of being thrown from a vicious horse while hunting at Fontainebleau. The style of Decamps was characteristically and intensely French. It was marked by vivid dramatic conception, by a manipulation bold and rapid, sometimes even to roughness, and especially by original and startling use of

England and Scotland, and generally among the Reformed (Calvinistic) churches and in the Greek Church, is known as the Philonic division (Philo *de Decalogo*, § 12). It is sometimes called by the name of Origen, who adopts it in his *Homilies on Exodus*. On this scheme the preface, Exod. xx. 2, has been usually taken as part of the first commandment. The Church of Rome and the Lutherans adopt the Augustinian division (Aug., *Quest. super Exod.*, lxxi.), combining into one the first and second commandments of Philo, and splitting his tenth commandment into two. To gain a clear distinction between the ninth and tenth commandments on this scheme it has usually been felt to be necessary to follow the Deuteronomic text, and make the ninth commandment, Thou shalt not covet thy neighbour's wife.¹ As scarcely any scholar will now claim priority for the text of Deuteronomy, this division may be viewed as exploded. But there is a third scheme (the Talmudic) still current among the Jews, and not unknown to early Christian writers, which is still a rival of the Philonic view. The preface, Exod. xx. 2, is taken as the first word, and the second embraces verses 3-6. Among recent Christian writers who have adopted this view are Knobel (in his *Com. on Exodus*) and Kuenen (*Gedachten van Israël*, i. 278 ff.). The decision between Philo and the Talmud must turn on two questions. Can we take the preface as a separate word? And can we regard the prohibition of polytheism and the prohibition of idolatry as one commandment? Now, though the Hebrew certainly speaks of ten "words," not of ten "precepts," it is most unlikely that the first word can be different in character from those that follow. But the statement "I am the Lord thy God," is either no precept at all, or only enjoins by implication what is expressly commanded in the words "Thou shalt have no other gods before me." Thus to take the preface as a distinct word is not reasonable unless there are cogent grounds for uniting the commandments against polytheism and idolatry. But that is far from being the case. The first precept of the Philonic scheme enjoins monolatry, the second expresses God's spiritual and transcendental nature. Accordingly Kuenen does not deny that the prohibition of images contains an element additional to the precept of monolatry, but, following De Goeje, regards the words from "thou shalt not make unto thyself" down to "the waters under the earth" as a later insertion in the original decalogue. Unless this can be made out—of which below—the Philonic scheme is clearly best, and as such it is now accepted by most scholars.

How were the ten words disposed on the two tables? The natural arrangement (which is assumed by Philo and Josephus) would be five and five. And thus, as Philo recognized, is a division appropriate to the sense of the precepts, for antiquity did not look on piety towards parents as a mere precept of probity, part of one's duty towards one's neighbour. The authority of parents and rulers is viewed in the Old Testament as a delegated divine authority, and the violation of it is akin to blasphemy (comp. Ex. xxi. 17, Lev. xx. 9, with Lev. xxiv. 15, 16, and note the formula of treason, 1 Kings xxi. 13).

We have thus five precepts of piety on the first table, and five of probity on the second, an arrangement which is accepted by the best recent writers. But the current view of the Western Church since Augustine has been that the precept to honour parents heads the second table. The only argument of weight in favour of this view is that it makes the amount of writing on the two tables less unequal, while we know that the second table as well as

the first was written on both sides (Ex. xxxii. 15). But we shall presently see that there may be another way out of this difficulty.

4. *Critical questions.*—That the decalogue not only contains Mosaic ideas; but is as old as Moses in its form as a system of "ten words," is admitted by critics of almost every school.² But it is much disputed what the original compass of the decalogue was. Did the whole text of Exod. xx. 2-17 stand on the tables of stone? The answer to this question must start from the reason annexed to the fourth commandment, which is different in Deuteronomy. But the express words "and he added no more," in Deut. v. 22, show that there is no conscious omission by the Deuteronomic speaker of part of the original decalogue, which cannot therefore have included the reason annexed in Exodus. On the other hand the reason annexed in Deuteronomy is rather a parenthetic addition than an original element dropped in Exodus. Thus the original fourth commandment was simply "Remember the Sabbath day to keep it holy."³ When this is granted it must appear not improbable that the elucidations of other commandments may not have stood on the tables. Thus in the second commandment, "Thou shalt not bow down to any visible form," &c., is a sort of explanatory addition to the precept "Thou shalt not make unto thee a graven image." And so the promise attached to the fifth commandment was probably not on the tables, and the tenth commandment may have simply been, "Thou shalt not covet thy neighbour's house," which includes all that is expressed in the following clauses. Such a view gets over the difficulty arising from the unequal length of the two halves of the decalogue. The elucidations (unless in the case of the fourth commandment) may very well be as old as Moses (comp. Ewald, *Geschichte*, ii. 229). It is quite another question whether there is any idea in the decalogue which cannot be as old as Moses. It is urged by many critics that Moses cannot have prohibited the worship of Jehovah by images, for the subsequent history shows us a descendant of Moses as priest in the idolatrous sanctuary of Dan. There were teraphim in David's house, and the worship of Jehovah under the image of a calf was the state religion of the kingdom of Ephraim. It is argued from these facts that image worship went on unchallenged, and that this would not have been possible had Moses forbidden it. This argument does not appear to have all the force that Kuenen and others attach to it, for it must be remembered how large a section of Christendom, in times much more advanced than those of the Old Testament, has accepted the decalogue and yet has worshipped images. And on the other side we have the much more cogent arguments that the number of ten words, which no one doubts to be primitive, cannot be naturally made out if the law against images is dropped, and that the existence of this law is necessary to explain the fact that the unquestionably Mosaic sanctuary of the ark, which is just the sanctuary of the revelation of the ten words, embodies the principle of the worship of Jehovah without images in a distinct and practical form. It may be added that the prohibition of images of hewn stone, which is the primitive sense of the word "graven-image," can hardly be less ancient than the conception that the stones of an altar were defiled by the touch of the chisel (Exod. xx. 24). And this is a conception which cannot be viewed as a later refinement on Mosaic ideas.

5. *The Decalogue of Exodus xxxiv.*—In the book of Exodus the words written on the tables of stone are nowhere expressly identified with the ten commandments of

¹ So, for example, Augustine, l. c. Thomas, *Summa (Prima Secunda)*, q. c. art. 4, and recently Sonntag and Kurtz. Purely arbitrary is the idea of Lutheran writers (Gerhard, *Loc. xlii.* § 46) that the ninth commandment forbids *concupiscentia actualis*, the tenth *concupiscentia originalis*.

² Exceptions to this consensus are Vatke (*Biblische Theologie*, p. 202) and Nöldeke (*Untersuchungen*, p. 51).

³ It is generally assumed that the addition in Exodus is from the hand that wrote Gen. i.-ii. 4.

chap. xx. In xxv. 16 xxxi. 18, xxxii. 15, we simply read of "the revelation" inscribed on the tables, and it seems to be assumed that the contents of this revelation must be already known to the reader. The expression "ten words" first occurs in xxxiv. 28, in a passage which relates the restoration of the tables after they had been broken. But these "ten words" are called "the words of the covenant," and so can hardly be different from the words mentioned in the preceding verse as those in accordance wherewith the covenant was made with Israel. And again, the words of verse 27 are necessarily the commandments which immediately precede in verses 12-26. Accordingly many recent critics, following Hitzig,¹ who seems to have formed his view without reference to a previous suggestion of Goethe's, have sought to show that Exod. xxxiv. 12-26 contains just ten precepts forming a second decalogue. In point of detail it is disputed whether the narrator of Exod. xxxiv. regards this decalogue as precisely identical with that which stood on the first tables (which seems to follow from xxxiv. 1) or as a modification of the original words (so Ewald). It does not seem possible to deny the connection of verses 27, 28 with one another and with the previous context as the text now stands. Hengstenberg (*Beitrag*, ii. 387 ff.) and Bertheau (*Sieben Gruppen Mosaischer Gesetze*, p. 97) seek to distinguish the words of verse 28, as written by God himself, from those which, in verse 27, Moses is commanded to write. But no such distinction lies in the text, and it is not probable that the narrator felt any contradiction between God's promise to write the words in verse 1 and the use of human instrumentality as implied in verse 28. On the other hand, the hypothesis of a second decalogue has serious if not insuperable difficulties. The number of ten precepts in Exod. xxxiv. is by no means clearly made out, and the individual precepts are variously assigned by different critics; while the most recent supporter of the theory admits that the original number of ten is now concealed by additions.² This supposed decalogue contains no precepts of social morality, but forms a sort of unsystematic abstract of the oldest laws about points of religious observance. If such a system of precepts was ever viewed as the basis of the covenant with Israel, it must belong to a far earlier stage of religious development than that of Exod. xx. This is recognized by Wellhausen, who says that our decalogue stands to that of Exod. xxxiv. as Amos stood to his contemporaries, whose whole religion lay in the observance of sacred feasts. But the idea that the ethical teaching of the prophets had no basis in the original document of the Mosaic covenant is so revolutionary that few will venture to accept "Goethe's decalogue" with such inferences. The difficulty is presumably due to the interweaving of several distinct narratives, which perplexes the sequence of many parts of Exodus. It is more probable that xxxiv. 10-27—a summary of the religious precepts of the Mosaic covenant—originally stood in a different connection than that there ever were two opinions as to what stood on the tables.

6. *The Decalogue in Christian Theology*.—Following the New Testament, in which the "commandments" summed up in the law of love are identified with the precepts of the decalogue (Mark x. 19; Rom. xiii. 9; cf. Mark xii. 28 ff.), the ancient church emphasized the permanent obligation of the ten commandments as a summary of *natural* in contradistinction to *ceremonial* precepts, though the observance of the Sabbath was to be taken in a spiritual sense (Augustine, *De Spiritu et Litera*, xiv.; Jerome, *De Celebratione Paschæ*). The mediæval theologians followed in the same line, recognizing all the pre-

cepts of the decalogue as moral precepts *de lege naturæ*, though the law of the Sabbath is not of the law of nature, in so far as it prescribes a determinate day of rest (Thomas, *Summa*, I^{ma} II^{da}, qu. c. art. 3; Duns, *Super Sententias*, lib. iii. dist. 37). The most important mediæval exposition of the decalogue is that of Nicolaus de Lyra, and the 15th century, in which the decalogue acquired special importance in the confessional, was prolific in treatises on the subject (Antoninus of Florence, Gerson, &c.).

Important theological controversies on the decalogue begin with the Reformation. The question between the Lutheran (Augustinian) and Reformed (Pulonic) division of the ten commandments was mixed up with controversy as to the legitimacy of sacred images not designed to be worshipped. The Reformed theologians took the stricter view. The identity of the decalogue with the eternal law of nature was maintained in both churches, but it was an open question whether the decalogue, as such (that is, as a law given by Moses to the Israelites), is of perpetual obligation. The Socinians, on the other hand, regarded the decalogue as abrogated by the more perfect law of Christ; and this view, especially in the shape that the decalogue is a civil and not a moral law (J. D. Michaelis), was the current one in the period of rationalism in last century. The distinction of a permanent and a transitory element in the law of the Sabbath is found, not only in Luther and Melancthon, but in Calvin and other theologians of the Reformed church. The main controversy which arose on the basis of this distinction was whether the prescription of one day in seven is of permanent obligation. It was admitted that such obligation must be not natural but positive; but it was argued by the stricter Calvinistic divines that the proportion of one in seven is agreeable to nature, based on the order of creation in six days, and in no way specially connected with anything Jewish. Hence it was regarded as a *universal positive* law of God. But those who maintained the opposite view were not excluded from the number of the orthodox. The laxer conception found a place in the Cocceian school.

Literature.—Geffcken, *Ueber die verschiedenen Eintheilungen des Dekalog's und den Einfluss derselben auf den Cultus*, Ewald's *History of Israel*, vol. ii.; Schultz's and especially Oehler's *Old Testament Theology*; Oehler's article "Dekalog" in Herzog's *Encyclopædie*, commentaries on Exodus, especially that of Knobel in German, and in English of Kalisch; Kuenen's *Godsdienst van Israel*, Hfdst. v. Kurtz, *Geschichte des Alten Bundes*, Bd. ii., other literature cited by Oehler and by Koehler, *Biblische Geschichte*, i. 287. For guidance in the theological controversies about the Decalogue the student may consult Walch and Baumgarten. (W. R. S.)

DECAMPS, ALEXANDRE GABRIEL (1803-1860), one of the foremost painters of the modern French school, was born in Paris on the 3d March 1803. He received his artistic training from Abel de Pujol, but set himself free at an early period of his career from academic trammels. He asserted his originality in his choice of subjects as well as in his style of treatment. In his youth he travelled in the East, and reproduced Oriental life and scenery with a bold fidelity to nature that made his works the puzzle of conventional critics. His powers, however, soon came to be recognized, and he was ranked along with Delacroix and Vernet as one of the leaders of the French school. At the Paris Exhibition of 1855 he received the grand or council medal. Most of his life was passed in the neighbourhood of Paris. He was passionately fond of animals, especially dogs, and indulged in all kinds of field sports. He died on the 22d August 1860 in consequence of being thrown from a vicious horse while hunting at Fontainebleau. The style of Decamps was characteristically and intensely French. It was marked by vivid dramatic conception, by a manipulation bold and rapid, sometimes even to roughness, and especially by original and startling use of

¹ *Ostern und Pfingsten im zweiten Dekalog*, Heidelberg, 1838

² Wellhausen in *Jahrb. f. D. Theol.*, 1876, p. 554.

decided contrasts of colour and of light and shade. His subjects embraced an unusually wide range. He availed himself of his travels in the East in dealing with scenes from scripture history, which he was probably the first of European painters to represent with their true and natural local background. Of this class were his Joseph sold by his Brethren, Moses taken from the Nile, and his scenes from the life of Samson, nine vigorous sketches in charcoal and white. Perhaps the most impressive of his historical pictures is his Defeat of the Cimbri, representing with wonderful skill the conflict between a horde of barbarians and a disciplined army. Decamps produced a number of genre pictures, chiefly of scenes from French and Algerine domestic life, the most marked feature of which is humour. The same characteristic attaches to most of his numerous animal paintings. He painted dogs, horses, &c., with great fidelity and sympathy, but his favourite subject was monkeys, which he depicted in various studies and sketches with a grotesque humour that could scarcely be surpassed. Probably the best known of all his works is *The Monkey Connoisseurs*, a clever satire of the jury of the French Academy of Painting, which had rejected several of his earlier works on account of their divergence from any known standard. The pictures and sketches of Decamps were first made familiar to the English public through the lithographs of Eugène la Roux. See Moreau's *Decamps et son Œuvre* (Paris, 1869).

DE CANDOLLE, AUGUSTIN PYRAMUS (1778–1841), a celebrated botanist, was born at Geneva, February 4, 1778. He was descended from one of the most ancient families of Provence, and his ancestors had been expatriated for their religion in the middle of the 16th century. His father was a famous printer, and syndic of the university and republic. Though a weakly boy he showed great aptitude for study, and distinguished himself at school by his rapid attainments in classical and general literature, and specially by a faculty for writing elegant verse, which led Florian to anticipate that he might become famous as a poet. He showed remarkable powers of memory, which proved of the greatest service to him in the science to which he ultimately devoted himself. His interest in plants was first roused while he was residing with his mother at a remote country village during the siege of Geneva in 1792. He began his scientific studies at the college of Geneva, by attending the courses of Saussure and Vaucler, the latter of whom first inspired him with the determination to make botanical science the chief pursuit of his life. In 1796 he removed to Paris, where he resided with Dolomieu, attended various courses of lectures on natural science, and gained the friendship of Jussieu and Desfontaines. His first productions, *Historia Plantarum Succulentarum* (4 vols., 1799) and *Astragalogia* (1802), introduced him to the notice of Cuvier (whose chair in the Collège de France he supplied in 1802), Humboldt, Biot, and Lamarck, who afterwards confided to him the publication of the third edition of the *Flore Française* (1803–15). The introduction to this work contained the first exposition of his principle of classification according to the natural as opposed to the Linnæan or artificial method. Having been elected (1804) doctor of medicine by the medical faculty of Paris, he wrote, as an inaugural work, the *Essai sur les propriétés médicinales des plantes comparées avec leurs formes extérieures et leur classification naturelle*, and soon after, in 1806, his *Synopsis plantarum in flora Gallica descriptarum*. At the desire of the French Government he spent the summers of the following six years in making a botanical and agricultural survey of the whole kingdom, the results of which he published in 1813. In 1807 he was appointed professor of botany in the medical faculty of the university of Montpellier, and in 1810 he was transferred to the newly founded chair of

botany of the faculty of sciences in the same university. He was an admirable lecturer, and the gardens under his charge were much improved during his occupancy of the chair. From Montpellier he removed to Geneva in 1816, having been invited by the now independent republic to fill the newly created chair of natural history. The rest of his life was spent in an attempt to elaborate and complete his "natural" system of botanical classification. The results of his labours in this department are to be found in his *Regni vegetabilis systema naturale*, of which two volumes only were completed (1821) when he found that it would be impossible for him to execute the whole work on so extensive a scale. He accordingly commenced in 1824 a less extensive work in the same direction—his *Prodromus systematis regni vegetabilis*,—but even of this he was able to finish only seven volumes, or two thirds of the whole. It was carried on after his death by his son Alphonse, who in 1834 had succeeded him in his professorship. He had been for several years in delicate health when he died on the 9th September 1841 at Turin, whither he had gone to attend a scientific reunion. De Candolle received diplomas or the honour of membership from most of the learned societies of Europe, and was a very frequent contributor to their Transactions. Louis Philippe decorated him with the cross of the Legion of Honour. He was highly esteemed in his native city, where he was for a long period rector of the academy and a member of the legislature. For an estimate of his place as a botanist see BOTANY, vol. iv. p. 80.

See Flournoy's *Éloge de Candolle* (1842), and De la Rive's *Candolle, sa Vie et ses Travailleurs* (1851).

DECAPOLIS, a district of Palestine, or perhaps rather a confederation of districts, situated, with the exception of a small portion, on the eastern side of the Upper Jordan and the Sea of Tiberias. Its boundaries are not accurately known, and probably were never precisely defined. It evidently takes its name from the fact that it included ten cities (δέκα πόλεις), but the ancient geographers do not agree as to which these ten cities were. This difference of statement may be explained by the supposition that, like the Cinque Ports of England, Decapolis preserved its original designation after new members were received into the confederation, and perhaps some of the old members had lost their connection. Pliny recognizes the uncertainty, but gives the following list:—Damascus, Philadelphia, Raphana, Scythopolis (on the west side of the Jordan), Gadara, Hippos, Dion, Pella, Galasa (Gerasa), and Canatha. Damascus is the only one that retains its importance; Scythopolis, or Beth Shean, which seems to have been anciently the next in size, is represented by the village of Beisan; and Gerasa, Canatha or Kenath, and Pella are of interest only for their ruins. Decapolis was placed by the Romans under the jurisdiction of the Syrian governor, and seems to have enjoyed special privileges. Regarding the rise and decay of the confederation we have no precise information, but it was at the height of its prosperity in the time of Christ.

DECATUR, a flourishing city of the United States, capital of Macon county, Illinois, situated in the midst of a rich agricultural district to the right of the Sangamon river, at a railway junction about 38 miles east of Springfield. It is well built, and has 15 churches and 24 public schools; but none of its edifices are individually remarkable. Among its industrial establishments is a large rolling mill. Population in 1870, 7161.

DECCAN (DĀKSHIN, the Country of the South), in India, includes, according to Hindu geographers, the whole of the territories situated to the south of the Nerbudda. In its more modern acceptation, however, it is sometimes understood as comprising only the

country lying between that river and the Krishna, the latter having for a long period formed the southern boundary of the Mahometan empire of Delhi. Assigning it the more extended of these limits, it comprehends the whole of the Indian peninsula, and in this view the mountainous system, consisting of the Eastern and Western Ghâts, constitutes the most striking feature of the Deccan. These two mountain ranges unite at their northern extremities with the Vindhya chain of mountains, and thus is formed a vast triangle supporting at a considerable elevation the expanse of table-land which stretches from Cape Comorin to the valley of the Nerbudda. The surface of this table-land slopes from west to east as indicated by the direction of the drainage of the country,—the great rivers the Canvery, Godavery, Krishna, and Pennaur, though deriving their sources from the base of the Western Ghâts, all finding their way into the Bay of Bengal through fissures in the Eastern Ghâts.

In early times this country embraced that possessed by the five Hindu princes of Telingana, Maharashtra, the Tamil country, Orissa, and Carnata or Bijayanagar. It was first invaded by the Mahometans in 1294, who stormed Deogiri, the capital of Maharashtra, and abandoned the city to pillage. In the year 1325 the Mahometans made further progress in its conquest; and having extirpated the Hindu dynasties, they annexed the provinces as far south as the Krishna to the empire of Delhi. The imperial sway was, however, of brief duration. Telingana and Carnata speedily reverted to their former masters; and this defection on the part of the Hindu states was followed by a general revolt, resulting in the establishment in 1347 of the independent Mahometan dynasty of Bahmani, and the consequent withdrawal of the power of Delhi from the territory south of the Nerbudda. In the struggles which ensued, the Hindu kingdom of Telingana fell to the Mussulmans, who at a later period formed a league against the remaining Hindu prince, and at the battle of Talikota in 1565 destroyed the monarchy of Bijayanagar or Carnata. On the dissolution of the Bahmani empire, its dominions were distributed into the five Mahometan states of Golconda, Bijapur, Ahmednagar, Beder, and Berar. Of these the larger succeeded in subverting those of less importance; and in 1630, during the reign of Shâh Jahân of Delhi, the greater proportion of the Deccan had been absorbed by the kingdoms of Golconda, Ahmednagar, and Bijapur. During the reign of Aurungzebe (in the latter half of the 17th century) all those states were reduced, and the Deccan was again annexed to the empire of Delhi. In the subsequent reigns, when the great empire of Aurungzebe fell into decay, the Nizâm threw off his allegiance and fixed his court at Hyderabad. At the same time the Mahrattas, emerging from obscurity, established a powerful monarchy, which was usurped by the Peshwa. The remainder of the imperial possessions in the peninsula were held by chieftains acknowledging the supremacy of one or other of these two potentates. In the sequel, Mysore became the prize of the Mahometan usurper Hyder Ali. During the contests for power which ensued about the middle of the last century between the native chiefs, the French and the English took opposite sides. After a brief course of triumph, the interests of France declined, and a new empire in India was established by the British. Mysore formed one of their earliest conquests in the Deccan. Tanjore and the Carnatic were shortly after annexed to their dominions. In 1818 the forfeited possessions of the Peshwa added to their extent; and these acquisitions, with others which have more recently fallen to the paramount power by cession, conquest, or failure of heirs, form a continuous territory stretching from the Nerbudda to Cape Comorin. Its length is upwards of 1000 miles, and its

extreme breadth exceeds 800. This vast tract comprehends the chief provinces now distributed between the presidencies of Madras and Bombay, together with the native states of Hyderabad and Mysore, and those of Kolapur, Sawantwâri, Travancore, Cochin, and the petty possessions of France and Portugal.

DECEMBER, the last month of the year. In the Roman calendar, traditionally ascribed to Romulus, the year was divided into ten months, the last of which was called December, or the *tenth* month, and this name, though etymologically incorrect, was retained for the last or twelfth month of the year as now divided. In the Romulan calendar December had thirty days; Numa reduced the number to twenty nine, Julius Cæsar added two days to this, giving the month its present length. The *Saturnalia* occurred in December, which is therefore styled "*acceptus genius*" by Ovid (*Fasti*, iii. 58); and thus also explains the phrase of Horace "*libertate Decembri utere*" (*Sat.* ii. 7). Martial applies to the month the epithet *canus* (hoary), and Ovid styles it *gelidus* (frosty) and *fumosus* (smoky). The Saxons called it *winter-monat*, or winter month, and *heligh-monat*, or holy month, from the fact that Christmas fell within it. The 22d December is the date of the winter solstice, when the sun reaches the tropic of Capricorn.

DECEMVIRI (*i.e.*, the ten men), ten magistrates of absolute authority among the Romans. Their appointment, according to Roman tradition, was due to plebeian dissatisfaction with the capricious administration of justice by the patricians, who had no written law to direct them. On the representation to the senate of the popular grievances by the tribunes, commissioners were sent to Greece to collect the laws of Solon and of the other celebrated legislators of Greece. On the return of these commissioners it was agreed, after much discussion, that ten new magistrates, called *decemviri*, should be elected from the senate to draw up a body of laws. Their election involved the abdication of all other magistrates; they were invested with supreme power, and presided over the city with regal authority. They were, each in turn, clothed with the badges of the consulship, and the one so distinguished had the power of assembling the senate and confirming its decrees. The first *decemviri* were chosen in the year 302 A.U.C. (451 B.C.) They arranged the laws by which their government was to be regulated in ten divisions, submitted them to the senate and comitia for their approbation, and, after the code was recognized as constitutional, administered it with so much moderation and efficiency that the continuance of the *decemviral* office for another year was unanimously voted. The second body of *decemviri* included one member of the first—Appius Claudius—and, according to Niebuhr, five plebeians. The new magistrates added to the laws which had already been enacted, and thus completed the celebrated *leges duodecim tabularum*, on which all Roman law, in future ages, was founded. Their administration, however, was as unpopular as that of their predecessors had been the reverse; and, by its partiality and injustice, which reached a climax in the flagitious pursuit of Virginia by Appius Claudius, it so roused the popular fury that the abolition of the office was effected. But, as Sir G. Cornewall Lewis has shown in his work on the *Credibility of Early Roman History*, it is difficult to write with scientific accuracy about this episode in Roman history. There were other magistrates in Rome, called *decemviri*, in regard to whose appointment and jurisdiction information is scanty. Scholars differ concerning the date of their institution, and the special functions of their office. There is evidence, however, that such a court existed during the empire; but it is uncertain whether the jurisdiction of the later coincided

with that of the earlier magistrates bearing the same name, and connected by some scholars, not only with the republic, but with the kings. There were also the *Decemviri Sibilini*, who were custodians of the Sibylline books. Their number, which originally consisted of two, and afterwards of ten, at last reached fifteen. It devolved on these functionaries not only to guard the Sibylline books, and to consult them on all emergencies of state, but also to take a prominent part in the celebration of the games of Apollo.

DECIMAL COINAGE It has often been proposed to substitute for our quarto-duodecimo-vicesimal system of reckoning money one entirely decimal, and therefore in harmony with the system, employed in all civilized countries, of reckoning numbers both integral and fractional. In the case of numbers, there is no difficulty in regard to the standard by which to reckon; it is unity, and all integral numbers are either so many units, tens of units, hundreds of units, &c., or combinations of these, and all fractional numbers either so many tenths of a unit, hundredths of a unit, &c., or combinations of these. In the case of money, however, the selection of the standard of value, or the unit by which to reckon, constitutes the main, if not the sole, theoretical difficulty to be overcome, previous to the introduction of a decimal coinage. Practical difficulties would arise from the unwillingness of people to make the changes in thinking and speaking that would be necessitated by new coins, or the altered values of old ones.

Of all the schemes proposed in England, that which advocates the retention of the sovereign, or pound sterling, as the unit of value seems to have met with most favour. According to this scheme, the pound would be divided into 10 florins the florin into 10 cents, and the cent into 10 mils. The name florin, as well as the coin, is in use already; the names cent and mil would mark the relation of the corresponding coins to the pound. The cent, being the $\frac{1}{100}$ th part of the pound, would represent $2\frac{1}{2}$ d., or nearly $2\frac{1}{2}$ d.; the mil, being the $\frac{1}{1000}$ th part, would be worth a little less than a farthing, which is the $\frac{1}{240}$ th. The coins which it would be found necessary to issue would probably be—in copper, the mil = $\frac{1}{2}$ d., the 2-mil piece = $\frac{1}{2}$ d., rather less than a halfpenny, and the 5-mil piece = $\frac{1}{2}$ d., rather less than a penny farthing; in silver, the cent = $2\frac{1}{2}$ d., the 2-cent piece = $4\frac{1}{2}$ d., the 5-cent piece, or shilling, and the 10-cent piece, or florin; in gold, the half-sovereign, and the sovereign. In addition to the preceding, perhaps a double florin = 4s., in silver, and a crown = 5s., in gold, might be found convenient.

The chief disadvantage of this system is that it would abolish the copper farthing, halfpenny, and penny, and the silver coins representing 3d., 4d., 6d. Since 6d. = 25 mils is the lowest number of pence which could be paid exactly in mils, inconvenience would thus be caused to the poorer classes, whose unit of value may be said to be the penny; and difficulties would also arise in cases where fixed imposts of a penny and a halfpenny are levied, such as penny and halfpenny tolls, postages, &c.

A second scheme advocates the adoption of the farthing as the unit of value, and its coins of account would be the farthing, the cent or doit = 10 farthings, the florin = 10 cents or doits, the pound = 10 florins. The coins required for circulation would probably be—in copper, the farthing, the halfpenny, the penny; in silver, the cent or doit = $2\frac{1}{2}$ d., the 2-cent piece or groat = 5d., the shilling = $12\frac{1}{2}$ d., and the florin = 25d., in gold, the half-sovereign = 10s. 5d., and the sovereign = 20s. 10d. Here also a silver double florin = 4s. 2d., and a gold crown = 5s. $2\frac{1}{2}$ d., might be found convenient.

The chief disadvantages of this system would be the abolition of the present pound sterling, the unit of value in national finance, in banks, insurance and all great com-

mercial offices, and the trouble that would thereby be caused in comparing values expressed in the old coinage with those of the new. Among its advantages may be reckoned the fact that, during the transition to the new state of things, the old coins would still be serviceable, for any sum of money expressed in the new coinage could be paid by means of them. The alterations on small imposts, requisite under the first scheme, would here be unnecessary; and inconvenience would be saved to those classes of the population who receive weekly wages, which are generally fixed at so many pence per hour. The reduction of sums expressed in the old coinage to their equivalents in the new would, however, be slightly more difficult than under the first system.

A third scheme proposes as the unit the half-sovereign, a coin almost as familiar as the sovereign, with the view of having only three instead of four coins of account. The half-sovereign would be divided into 10 shillings as at present, and the shilling into 10 pence, each of which would therefore be equivalent to $1\frac{1}{2}$ d., or 20 per cent. more than the present penny. As a penny is of more value than the metal of which it is made, the present copper coinage could be made to serve under the new system. This scheme, from its alteration of the value of the penny, is open to most of the objections that can be brought against the first; and, in comparing accounts expressed in the old and the new coinages, it would necessitate—a very slight inconvenience certainly—multiplication or division by 2.

A fourth scheme proposes that the penny be made the unit of value, and that all accounts should be kept in tenpences and pence. All the present coins, though only one of them would be a coin of account, could still remain in circulation; and only two new coins would be required, the tenpence and its half, fivepence.

It has also been proposed that there should be only two coins of account, the higher equivalent to 100 of the lower, such as florins and cents, the cent in this scheme being the mil of the first. Centesimal coinage similar to this exists in several foreign countries, &c.; but it is probable that, should a change be made, the practice of other nations will be imitated only where it is found to conduce to national convenience.

The preceding are the most important of the schemes that have been suggested to replace the present system, and the adoption of the first of them has been recommended by a committee of the House of Commons. But since 1855 public opinion on the question does not appear to have advanced much. The arguments for and against a change are numerous, and to detail them would be to fill a moderate volume. The principal reason for making the change is that calculation would be enormously simplified, for reduction from one denomination of money into another could always be performed at sight; and the compound rules, as far as money is concerned, would be virtually abolished. The greatest objections to the change, apart from the difficulty of getting people to make it, which is doubtless much exaggerated, are that a decimal system does not admit to a sufficient extent of binary subdivision, and that it does not admit of ternary subdivision at all. The third part, for instance, of a pound, of a florin, of a cent, being $33\frac{1}{3}$, $33\frac{1}{3}$, $3\frac{1}{3}$ mils respectively, could not be exactly paid in decimal currency, while there is no difficulty in paying the third part of a pound, or of a shilling by our present coinage. Again, the $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{6}$ of the pound, the $\frac{1}{2}$, $\frac{1}{3}$ of the florin, and the $\frac{1}{2}$ of the cent are the only binary subdivisions possible with the decimal coins of account; the $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, $\frac{1}{64}$ of the pound, and the $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ of the shilling are possible at present. Notwithstanding these drawbacks, the advantages of a decimal system seem con-

siderably to preponderate, and the introduction of it to be merely a question of time.

The coinage of the United States, which was made decimal in 1786, consists of the eagle = 10 dollars, the dollar = 10 dimes, the dime = 10 cents, but of these denominations dollars and cents are the only ones commonly used. In France, shortly after the great Revolution, a decimal system not only of money, but also of weights and measures, was introduced. The standard of value is the franc = 100 centimes; but though the only coins are francs, centimes, and multiples of these, the word *son*, a term belonging to the superseded coinage, is often used to denote the 20th part of the franc, or 5 centimes. The Belgian and the Swiss monetary systems were assimilated to that of France in 1833 and 1851; and in 1865 France, Italy, Belgium, and Switzerland, became parties to a treaty for the maintenance of a common system. Germany, within the last few years, has effected a reform of her currency, the mark, which corresponds closely to our shilling, being = 10 groschen = 100 pfennige. A decimal coinage exists also in Russia, where the ruble = 100 kopecks; in Holland, where the guilder = 10 dubbeltjes = 100 cents; and in Portugal, where the milrei = 1000 reis.

See *Observations on the Expediency and Practicality of Simplifying and Improving the Measures, Weights, and Money, &c.*, by General Sir Charles Pasley, Bart, 1834; the Report of the Select Committee on a Decimal System of Coinage, August 1833; and the publications of the "Decimal Association." DECIUS MUS See Mrs.

DECLARATION in an action at law was the first step in pleading—the formal statement of the matter in respect of which the defendant sued. It was divided into counts, in each of which a specific cause of action was alleged, but the language used was cautious and general, and the same matter might be the subject of several counts. By the simpler form of pleading established by the Judicature Act, 1873, the declaration is replaced by a statement of claim setting forth the simple facts on which the plaintiff relies.

Statutory declaration.—By 5 and 6 Will. IV. c. 62 (which was an Act to make provisions for the abolition of unnecessary oaths, and to repeal a previous Act of the same session on the same subject) various cases are specified in which a declaration shall be substituted for an affidavit on oath. There is a general clause empowering any justice of the peace, notary public, or other officer now by law authorized to administer an oath, to take and receive the declaration of any person voluntarily making the same before him in the form in the schedule to the Act annexed; and if any declaration so made shall be false or untrue in any material particular, the person wilfully making such false declaration shall be deemed guilty of a misdemeanor.

DECLARATION OF PARIS, a diplomatic instrument or protocol signed by the representatives of all the powers present at the Congress of Paris in 1856, and subsequently accepted as a binding engagement of public law by all the other powers (except the United States of America, Spain, and Mexico), for the purpose of settling and defining certain rules of maritime law, in time of war, on points of great moment to belligerent and neutral states—points, it must be added, upon which the ancient law of nations had gradually undergone some change, and on which great differences of opinion and practice prevailed. The four propositions agreed to by the plenipotentiaries were embodied in the following terms:—

1. Privateering is and remains abolished
2. The neutral flag covers enemy's goods, with the exception of contraband of war.
3. Neutral goods, with the exception of contraband of war, are not liable to capture under an enemy's flag
4. Blockades, in order to be binding, must be effective,—that is to say, maintained by a force sufficient readily to prevent access to the coast of the enemy.

By most of the modern writers on international law these principles are regarded as a distinct gain to the cause of civilization, international justice, commerce, and peace. But a feeble and ineffectual attempt has been made to repudiate these new rules of maritime law, though they received the tacit assent of Parliament, and have been acted upon by all nations in the six wars which have occurred since 1856, including the American civil war, although the United States had not concurred in the Declaration. The American Government withheld its assent, not because it objected to these principles, but because it held that they did not go far enough, and that they ought to be extended to secure from capture all private property at sea. It is argued by the opponents of the Declaration that the British envoy at Paris exceeded his powers; that the form of the instrument itself is declaratory, but not binding either as a contract or a legislative act; that it is not competent to a congress to change the rights of belligerents founded on ancient law and usage; and that Great Britain committed a fatal error in renouncing the right to seize enemy's goods in neutral ships and to equip privateers.

To these arguments it is said in reply that the British envoy at Paris had full powers to pledge the faith of the Crown, with the concurrence of the Cabinet, and that if Parliament disapproved his conduct, it ought to have been pressed to a division at the time, and not when Great Britain has enjoyed the benefit of the Declaration, as a neutral, for twenty years. It is a part of the prerogative of the Crown to fix our international relations, and to determine the conditions of maritime warfare. The most fitting and binding expression of international law (which cannot assume the form of positive law by sovereign enactment) is to be found in instruments recording in solemn form the consent of all civilized nations. On the ground of expediency, it is contended by the supporters of the Declaration of Paris, that Great Britain is, of all countries in the world, that which has most to gain by it, because she is not only the greatest naval power, but the power which has the largest number of merchant vessels and the largest amount of property afloat on the seas, and liable to attack.

The primary advantage of the Declaration no doubt accrues to neutrals, as it secures to them a larger carrying trade in time of war, and exempts them from the seizure of enemy's goods in neutral ships. Hence, if a belligerent were now to violate the rules of the Declaration, he would have to encounter the opposition of all neutral states, and would speedily find them arrayed on the side of the enemy. But in the event of war, Great Britain is the state most exposed, by reason of the magnitude of her maritime trade, to the depredations of hostile cruisers; the injury done is to be measured by the amount of the shipping and property exposed to it; and a single cruiser of a small state may cause enormous losses to the commerce of a great power, as was seen in the American civil war. Since the establishment of a general system of railroads, the greater part of the trade of all the states of continental Europe can be carried on by land, either by direct communication or through neutral ports. The power of a naval state to inflict serious injury on an enemy by the interruption of her trade is therefore by the nature of things greatly diminished, and the same remark applies to commercial blockades. To England all foreign commodities must be brought by sea, and England is more dependent than any other country on foreign trade for the raw material of her manufactures, and even for the food of her inhabitants. It is therefore the paramount interest of England to keep open all the channels of trade, as much as possible, both in peace and war; and injuries done to the trade of an enemy are often equally prejudicial to the state which

inflicts them. These are some of the leading arguments which have been advanced in defence of the Declaration of Paris, and which no doubt actuated the authors of it.

A full account of the controversy will be found in the third volume of Sir Robert Phillimore's *Commentaries on International Law*, where the learned author supports and advocates the old traditions of the Court of Admiralty, and also in Hall's *Rights and Duties of Neutrals* (1874). The principles on which the Declaration of Paris is based are explained and defended in an article in the *Edinburgh Review*, No 296 (H. R.)

DECLARATOR, in Scotch law, is a form of action by which some right of property, or of servitude, or of status, or some inferior right or interest, is sought to be judicially declared (see Bell's *Dictionary and Digest of the Law of Scotland*).

DECREE, DECREET, the judgment of a court of justice, and, in English law, more particularly the judgment of a court of equity. A decree *nisi* is the conditional order for a dissolution of marriage made by the court for divorce and matrimonial causes, which will be made absolute after six months, in the absence of sufficient cause shown to the contrary.

DECRETALS, in canon law, are the answers sent by the Pope to applications made to him as head of the church, chiefly by bishops, but also by synods, and even private individuals, for guidance in cases involving points of doctrine or discipline. In the early days of the church these replies came to be circulated throughout the various dioceses, and furnished precedents to be observed in analogous circumstances. From the 4th century onwards they formed the most prolific source of canon law. Decretals (*decreta constituta decretalia, epistolæ decretales*, or shortly *decretalia*, or *decretales*) ought, properly speaking, to be distinguished, on the one hand from constitutions (*constitutiones pontificiæ*), or general laws enacted by the Pope *sua sponte* without reference to any particular case, and on the other hand from rescripts (*rescripta*), which apply only to special circumstances or individuals, and constitute no general precedent. But this nomenclature is not strictly observed.

For further information see art. **CANON LAW**, in which will also be found an account of the *Pseudo-Isidorian* or *False Decretals*.

DECURIO, an officer in the Roman cavalry, commanding a decuria, which was a body consisting of ten men. There were certain provincial magistrates called *decuriones municipales*, who had the same position and powers in free and corporate towns as the senate had in Rome. As the name implies, they consisted at first of ten, but in later times the number was often as many as a hundred; their duty was to watch over the interests of their fellow-citizens, and to increase the revenues of the commonwealth. Their court was called *curia decurionum*, and *minor senatus*; and their decrees, called *decreta decurionum*, were marked with D. D. at the top. They generally styled themselves *civitatum patres curiales*, and *honorati municipiorum senatores*. They were elected with the same ceremonies as the Roman senators, and they required to be at least twenty-five years of age, and to be possessed of a certain fixed income. The election took place on the kalends of March.

DEE, JOHN (1527–1608), a mathematician and astrologer, was born in July 1527, in London, where his father was a wealthy vintner. In 1542 he was sent to St John's College, Cambridge. After five years' close application to mathematical studies, particularly astronomy, he went to Holland, in order to visit several eminent Continental mathematicians. Having remained abroad nearly a year, he returned to Cambridge, and was elected a fellow of Trinity College, then first erected by King Henry VIII. In 1548 he took the degree of master of arts, but in the same year he found it necessary to leave England on account of the suspicions entertained of his being a conjuror,

which were first excited by a piece of machinery, in the *Irene* of Aristophanes, he exhibited to the university, representing the scarabæus flying up to Jupiter, with a man and a basket of victuals on its back. On leaving England he went first to the university of Louvain, where he resided about two years, and then to the college of Rheims, where he read lectures on Euclid's *Elements* with great applause. On his return to England in 1551 King Edward assigned him a pension of 100 crowns, which he afterwards exchanged for the rectory of Upton-upon-Severn. Soon after the accession of Mary, he was accused of using enchantments against the queen's life, but after a tedious confinement, he obtained his liberty in 1555, by an order of council.

When Elizabeth ascended the throne, Dee was asked by Lord Dudley to name a propitious day for the coronation. On this occasion he was introduced to the queen, who took lessons in the mystical interpretation of his writings, and made him great promises, which, however, were never fulfilled. In 1564 he again visited the Continent, in order to present a book which he had dedicated to the Emperor Maximilian. He returned to England in the same year, but in 1571 we find him in Lorraine, whither two physicians were sent by the queen to his relief in a dangerous illness. Having once more returned to his native country, he settled at Mortlake, in Surrey, where he continued his studies with unremitting ardour, and made a collection of curious books and manuscripts, and a variety of instruments, most of which were destroyed by the mob during his absence, on account of his supposed familiarity with the devil. In 1578 Dee was sent abroad to consult with German physicians and astrologers in regard to the illness of the queen. On his return to England, he was employed in investigating the title of the Crown to the countries recently discovered by British subjects, and in furnishing geographical descriptions. Two large rolls containing the desired information, which he presented to the queen, are still preserved in the Cottonian Library. A learned treatise on the reformation of the calendar, written by him about the same time, is still preserved in the Ashmolean Library at Oxford.

From this period the philosophical researches of Dee were concerned entirely with the pseudo-science of necromancy. In 1581 he became acquainted with Edward Kelly, an apothecary who professed to have discovered the philosopher's stone, and by whose assistance he performed various incantations, and maintained a frequent imaginary intercourse with spirits. Shortly after, Kelly and Dee were introduced to a Polish nobleman, Albert Laski, palatine of Sieradz (Sieradz), devoted to the same pursuits, who persuaded the two friends to accompany him to his native country. They embarked for Holland in September 1583, and arrived at Laski's place of residence in February following. They lived for some years in Poland and Bohemia in alternate wealth and poverty, according to the credulity or scepticism of those before whom they exhibited. They professed to raise spirits by incantation. Kelly dictated their utterances to Dee, who wrote them down and interpreted them.

Dee, having at length quarrelled with his companion, quitted Bohemia and returned to England, where he was made chancellor of St Paul's Cathedral in 1594, and warden of Manchester College in 1595. He afterwards returned to his house at Mortlake, where he died in 1608, at the age of eighty-one.

His principal works are—*Propædæmata Aphoristica*, Lond 1558, *Monas Hieroglyphica*, Antwerp, 1564, *Epistola ad Fredericum Commandinum*, Pesaro, 1570, *Preface Mathematica to the English Euclid*, 1570, *Divers Annotations and Inventions added after the tenth book of English Euclid*, 1570, *Epistola præfixa Ephemeridibus Joannis Fildi*, a 1557, *Parallatice Commentationis Praæcos-*

que Nucleus quidam, London, 1573. The catalogue of his printed and published works is to be found in his *Compendious Rehearsal*, as well as in his letter to Archbishop Whitgift, to which the reader is referred. A manuscript of Dec's, relating what passed for many years between him and some spirits, was edited by Meric Casaubon and published in 1659. *The Private Diary of Dr John Dec*, and the *Catalogue of his Library of Manuscripts*, edited by J. O. Halliwell, was published by the Camden Society in 1842.

DEED is a contract in writing, sealed and delivered by the party bound to the party benefited. Contracts or obligations under seal are called in English law *specialties*, and down to a recent date they took precedence in payment over *simple* contracts, whether written or not. Writing, sealing, and delivery are all essential to a deed. The signature of the party charged is not material, and the deed is not void for want of a date. Delivery, it is held, may be complete without the actual handing over of the deed; it is sufficient if the act of sealing were accompanied by words or acts signifying that the deed was intended to be presently binding; and delivery to a third person for the use of the party benefited will be sufficient. On the other hand, the deed may be handed over to a third person as an *escrow* (*écrit*), in which case it will not take effect as a deed until certain conditions are performed. Such conditional delivery may be inferred from the circumstances attending the transaction, although the conditions be not expressed in words. A deed indented, or indenture (so called because written in counterparts on the same sheet of parchment, separated by cutting a wavy line between them), is between two or more parties who contract mutually. The actual indentation is not now necessary to an indenture. A *deed-poll* (without indentation) is a deed in which one party binds himself without reference to any corresponding obligations undertaken by another party. See CONTRACT.

DEER (*Cervidae*), a family of Ruminant Artiodactyle Mammals, distinguished by the possession of deciduous branching horns or antlers, and by the presence of spots on the young. The antlers are borne by the frontal bone, and generally begin to appear towards the end of spring. At that season there is a marked determination of blood to the head, the vessels surrounding the frontal eminences become temporarily enlarged, and the budding horn grows with marvellous rapidity, the antlers of a full-grown stag being produced in ten weeks. At first the horns are soft, vascular, and highly sensitive, and are covered with a delicate hairy integument known as the "velvet," amply provided with blood-vessels. On attaining their full growth the "burr," consisting of a ring of osseous tubercles at the base of the horn, is formed, and this by pressing upon, gradually cuts off the blood-vessels which supply nutriment to the antlers. The velvety covering then begins to shrivel and to peel off, its disappearance being hastened by the deer rubbing its antlers against trees and rocks; while the grooves, which are seen to furrow the now exposed surface, mark the place of the former blood-vessels. With the single exception of the reindeer, antlers are confined to the male sex, and are fully developed at the commencement of the rutting season, when they are brought into use as offensive weapons in the sanguinary fights between the males for possession of the females. When the season of love is over they are shed, reappearing, however, in the following spring, and continuing to grow larger and heavier until the deer attains its full growth. Whether the deer inhabiting the warmer regions of the earth shed their antlers every year has been a matter of considerable dispute, but in a recent work (*Highlands of Central India*) Forsyth states that he has convinced himself, from repeated observations, that in Indian deer this operation does not take place annually. In castrated animals the antlers either cease to appear or are merely rudimentary, while any influence whatever which disturbs the general

system seems detrimental to their growth, as was observed in a case quoted by Darwin, where the antlers of a Wapiti deer, formed during a voyage from America, were singularly stunted, although the same individual afterwards, when living under normal conditions, produced perfect horns. Spots are common to the young of so many species of deer that their presence may fairly be regarded as a family character. These spots persist through life in such forms as the Axis, or Spotted Deer (*Axis maculata*), but in the majority of species they altogether disappear in the adult form. Darwin considers that in all such cases the old have had their colour changed in the course of time, while the young have remained but little altered, and this he holds has been effected "through the principle of inheritance at corresponding ages." The lachrymal sinus, or "tearpit," is present in most species of deer. This consists of a cavity beneath each eye, capable of being opened at pleasure, in which a waxy substance of a disagreeable odour is secreted, the purpose of which is not yet clearly ascertained. "The big round tears" which the contemplative Jacques watched, as they

"Coursed one another down his innocent nose
In piteous chase,"

is Shakespeare's interpretation of the appearance presented by the motion of the glistening edges of the tearpits in the stag. The deer family comprises 8 genera and 52 species, distributed over all the great regions of the earth except the Ethiopian, and living under the most diverse climatic conditions. Their total absence from Africa south of the Sahara may be due, as A. R. Wallace (*Geographical Distribution of Animals*) contends, to the presence in the past, as now, of a great belt of dry and desert country effectually preventing the immigration from Europe into Africa of such a forest-frequenting group as the deer, while favouring the introduction of antelopes, which attain their greatest development in that region. They are also absent from Australia, although present in the Austro-Malayan region. The following are some of the more remarkable species.

The Red Deer or Stag (*Cervus elaphus*), the largest of the British deer, is a native of the temperate regions of Europe and Northern Asia, inhabiting dense forests, or frequenting moors and barren hill-sides as in Scotland. In England, where in feudal times it was protected by forest laws, which set greater value on the life of a stag than on that of a man, it was formerly abundant in all the royal forests. It is now almost extinct in that country, as well as in Ireland, in the wild state. In Scotland considerable herds are still to be found in the Highlands, and in several of the Western Isles, although, owing probably to the diminished extent of their feeding grounds, to the breeding in and in which takes place, and to the anxiety of deer-stalkers to secure the finest heads, the species is believed to be degenerating. The finest specimens in this country are found in the deer forests of Sutherlandshire, but these are inferior in size to those still obtained in the east of Europe. The antlers of the Stag are rounded, and bear three "tines," or branches, and a crown consisting of three or more points. The points increase in number with the age of the creature, and when 12 are present it is known in Scotland as a "royal stag." This number, however, is sometimes exceeded, as in the case of a pair of antlers, weighing 74 lb, from a stag killed in Transylvania, which had 45 points. The antlers during the second year consist of a simple unbranched stem, to which a tine or branch is added in each succeeding year, until the normal development is attained, after which their growth is somewhat irregular. The Red Deer is gregarious, the females and calves herding together apart from the males except at the rutting season, which begins about the end of September and lasts for three weeks. Dur-

Brunswick in the south. There are several well-marked varieties differing greatly in size, and in the form of the antlers—the largest forms occurring furthest north, while by many writers the American reindeer, which has never been domesticated, is regarded as a distinct species. The antlers, which are long and branching, and considerably palmated, are present in both sexes, although in the female they are more slender and less branched than in the males. In the latter they appear at a much earlier age than in any other species of deer, and Darwin conjectures that in this circumstance a key to their exceptional appearance in the female may be found. The reindeer has long been domesticated in Scandinavia, and is of indispensable importance to the Lapland race, to whom it serves at once as a substitute for the horse, cow, sheep, and goat. As a beast of burden it is capable of drawing a weight of 300 lb, while its fleetness and endurance are still more remarkable. Harnessed to a sledge it will travel without difficulty 100 miles a day over the frozen snow, its broad and deeply cleft hoofs being admirably adapted for travelling over such a surface. During summer the Lapland reindeer feeds chiefly on the young shoots of the willow and birch; and as at this season migration to the coast seems necessary to the well-being of the species, the Laplander, with his family and herds, sojourns for several months in the neighbourhood of the sea. In winter its food consists chiefly of the reindeer moss and other lichens, which it makes use of its hoofs in seeking for beneath the snow. The wild reindeer grows to a much greater size than the tame breed, but in Northern Europe the former are being gradually reduced through the natives entrapping and domesticating them. The tame breed found in Northern Asia is much larger than the Lapland form, and is there used to ride on. There are two distinct varieties of the American reindeer—the Barren Ground Caribou, and the Woodland Caribou. The former, which is the larger and more widely distributed of the two, frequents in summer the shores of the Arctic Sea, retiring to the woods in autumn to feed on the tree and other lichens. The latter occupies a very limited tract of woodland country, and, unlike the Barren Ground form, migrates southward in spring. The American reindeers travel in great herds, and being both unsuspicious and curious they fall ready victims to the bow and arrow or the cunning snare of the Indian, to whom their carcasses form the chief source of food, clothing, tents, and tools. Remains of the reindeer are found in caves and other Post-Pliocene deposits as far south as the south of France, this boreal species having been enabled to spread over Southern Europe, owing to the access of cold during the glacial period. It appears to have continued to exist in Scotland down even to the 12th century.

The Muntjac (*Cervulus vaginalis*) has its two pronged horns placed on permanent bony pedestals 3 inches in length, and the male is further furnished with long canines in the upper jaw. It is a native of Java, where it may occasionally be seen in the inclosures of Europeans, but, according to Dr Horsfield, it is impatient of confinement, and not fit for the same degree of domestication as the stag. Its flesh forms excellent venison. There are four species of muntjacs inhabiting the forest districts from India to China, and southward to Java and the Philippine Islands.

The Musk Deer (*Moschus moschiferus*) differs from the true deer in the absence of horns, and in the presence of the musk-bag, and is now usually regarded as the type of a distinct family—*Moschidae*. The young, however, are spotted as in the *Cervidae*, and it is doubtful whether the differences already mentioned are sufficient to warrant its separation from the other deer. Canine teeth are present in the upper and lower jaws of both sexes, those in the

upper jaw of the male being longest. It is a native of the highlands of Central Asia from the Himalayas to Peking, being found at an elevation of 8000 feet, and in its habit resembling such mountain species as the chamois. It is exceedingly shy and difficult of approach, and is hunted solely for its musk—an unctuous brown secretion, possessing a most penetrating and enduring odour, extremely disagreeable when present in large quantities, but forming a pleasant perfume when used sparingly. The substance is contained in a bag, almost the size of a hen's egg, situated on the abdomen, and secreted in greatest quantity during the rutting season. The hunters cut off the bag, and close the opening, and after drying, it is ready for sale.

Fossil Deer.—Remains of many extinct species of deer belonging to existing genera have been found in Post-Pliocene and other recent deposits; while the remains of extinct genera occur in both hemispheres, but do not extend further back than the Upper Miocene. The deer family, so far as yet discovered, is thus of comparatively recent origin, and is probably, as Mr Wallace suggests, an Old World group, which during the Miocene period passed to North America and subsequently to the southern continent. The best preserved species of fossil deer is the gigantic Irish Elk (*Cervus megaceros*). It is not a true elk, but is intermediate between the fallow deer and reindeer, and is found in great abundance and perfection in the lake deposits of Ireland. It occurs also in the Isle of Man, in Scotland, and in some of the English caverns. The antlers of a specimen of this species in Dublin weigh about 80 lb, and their span is twice that of the living elk. It appears to have been contemporaneous with the extinct mammoth and rhinoceros, but it is still doubtful whether it co-existed with man. In Kent's Hole, near Torquay, the base of an antler, partly gnawed, was found; and this, according to Owen, probably belonged to the most gigantic of our English cervine animals. (J G1)

DEFAMATION, saying or writing something of another, calculated to injure his reputation or expose him to public hatred, contempt, and ridicule. See LIBEL and SLANDER.

DEFENDER OF THE FAITH (*Fidel Defensor*), a peculiar title belonging to the sovereign of England, in the same way that *Catholicus* belongs to the king of Spain, and *Christianissimus* to the king of France. Although certain charters have been appealed to in proof of an earlier use of the title, it appears to have been first conferred by Leo. X. on Henry VIII. in 1521 for writing against Luther. It was afterwards confirmed by Clement VII. When Henry suppressed the religious houses at the time of the Reformation, the Pope not only deprived him of this designation, but also deposed him; in the thirty-fifth year of his reign, however, the title of "Defender of the Faith" was confirmed by Parliament, and has continued to be used by all his successors on the English throne.

DEFFAND, MARIA DE VICHY-CHAMOND, MARQUISE DU (1697–1780), a celebrated leader in the fashionable literary society of Paris during the greater part of the 18th century, was born in Burgundy of a noble family in 1697. Educated at a convent in Paris, she there displayed, along with great intelligence, the sceptical and cynical turn of mind which so well suited the part she was afterwards to fill in the philosophical circles of Paris. Her parents, alarmed at the freedom of her views, arranged that Massillon should visit and reason with her, but this seems to have had little effect. They married her at twenty-one years of age to the Marquis du Deffand without consulting her inclination. The union proved an unhappy one, and resulted in a speedy separation. Madame du Deffand, young and beautiful, did not, according to the common belief, succeed in keeping herself uncontaminated by the abounding vice of the age, and it is said that she was for

a time the mistress of the regent. She was afterwards reconciled to her husband, but it proved impossible for them to live together, and a second and final separation took place. Without heart and without enthusiasm, Madame du Deffand was incapable of any strong attachment, but her intelligence, her cynicism, and her *esprit* made her the centre of attraction to a circle which included nearly all the famous philosophers and literary men in Paris, besides not a few distinguished visitors from abroad. In 1752 she became blind, and soon afterwards she took up her abode in apartments in the convent of St Joseph in the Rue St Dominique, which had a separate entrance from the street. This became the frequent resort of such men as Choiseul, Boufflers, Montesquieu, Voltaire, D'Alembert, David Hume, and Horace Walpole. In 1764 the society was split into two parties by the defection of her companion Mademoiselle de L'Espinasse, who took with her D'Alembert and several others. Madame du Deffand had most affinity of nature with Horace Walpole, who paid several visits to Paris expressly for the purpose of enjoying her society, and who maintained a close and most interesting correspondence with her for fifteen years. She died on the 24th September 1780. Of her innumerable witty sayings probably the best, and certainly the best known, is her remark on the Cardinal de Polignac's account of St Denis's miraculous walk of two miles with his head in his hands,—“Il n'y a que le premier pas qui coûte.”

The correspondence of Madame du Deffand with D'Alembert, Hénault, Montesquieu, and others was published at Paris in 1809. Her letters to Horace Walpole, edited, with a biographical sketch, by Miss Berry, were published at London from the originals in Strawberry Hill in 1810.

DEFOE, DANIEL (1661–1731), was born in London in the year 1661, in the parish of St Giles, Cripplegate. Neither the exact date nor place of his birth is known, nor is his baptism recorded, probably because he was of a non-conformist family. Hardly anything is known of his ancestors, his grandfather, Daniel Foe, is said to have been a squire or wealthy yeoman at Elton, in Huntingdonshire (not Northamptonshire, as more generally stated), and to have kept a pack of hounds; but the authority for the former statement seems to be mainly traditional, and for the latter we have merely an anecdote in one of Defoe's newspaper articles, which is at least as likely to have been fiction as fact. Attempts have been made, but merely fancifully, to trace the name to Vaux, Fawkes, or even Devereux. As to the variation Defoe or Foe it is to be noticed that its owner signed either indifferently till a late period of his life, and that his initials where they occur are sometimes D. F. and sometimes D. D. F. Mr Lees conjectures, that the later form originated in his being called Mr D. Foe to distinguish him from his father, seems not unlikely. It may be added that three autograph letters of his are extant, all addressed in 1705 to the same person, and signed respectively D. Foe, de Foe, and Daniel Defoe.

James Foe, the father of the author of *Robinson Crusoe*, was a butcher and a citizen of London. Of his mother nothing is known. Daniel was chiefly educated at a famous dissenting academy, Mr Morton's of Stoke Newington, where many of the celebrated nonconformists of the time were brought up. It is noteworthy that one of his schoolfellows suggested the unusual name of Crusoe. In after life Defoe frequently asserted the sufficiency of his education and the excellence of the methods observed by his teacher. Judging from his writings his stock of general information must have been far larger than that of most regularly educated men of his day; but it is probable that his attainments were in no particular line very exquisite or profound. With very few exceptions all the known events of Defoe's life are connected with authorship. In the older catalogues of his works two pamphlets, *Speculum*

Crapegnorum (a satire on the clergy) and *A Treatise against the Turks*, are attributed to him before the accession of James II, but there seems to be no publication of his which is certainly genuine before *The Character of Dr Amesley*, the family minister, published in 1697. He had, however, before this (if we may trust tradition) played an active part in public affairs. He had taken up arms in Monmouth's expedition, and is supposed to have owed his lucky escape from the clutches of the king's troops and the law, into which not a few of his school-fellows fell, to the fact of his being a Londoner, and therefore a stranger in the west country. On January 26, 1688, he was admitted a liveryman of the city of London, having claimed his freedom by birth. Since his western escapade he had taken to the business of wholesale hosiery. At the entry of William and Mary into London he is said to have served as a volunteer trooper “gallantly mounted and richly accoutred.” In these days he lived at Tooting, and was instrumental in forming a dissenting congregation at that place. His business operations at this period appear to have been extensive and various. He would seem both now and later to have been a sort of commission merchant, especially in Spanish and Portuguese goods, and at some time or other he visited Spain on business. Later we hear him spoken of as “a civet-cat merchant,” but as he can hardly have kept a menagerie of these animals it is odd that no one has supposed that the civet-cat was the sign of his place of business (it was a very usual one) rather than the staple of his trade. In 1692 his mercantile operations came to a disastrous close, and he failed for £17,000. By his own account the disaster would seem to have arisen from relying too much on credit. His misfortunes made him write both feelingly and forcibly on the bankruptcy laws; and although his creditors accepted a composition, he afterwards honourably paid them in full, a fact attested by independent and not very friendly witnesses. Subsequently, he undertook first the secretaryship and then the managership and chief ownership of some tile-works at Tilbury, but here also he was unfortunate, and his imprisonment (of which more hereafter) in 1703 brought the works to a stand-still, and thereby lost him £3000. From this time forward we hear of no settled business in which he engaged. He evidently, however, continued to undertake commissions, and made his political visits to Scotland an occasion for opening connections of this kind with that country. In the last thirty years of his life business played but a subordinate part, though he seems to have derived more profit from it than from his earlier ventures. It was probably at the time of his troubles in 1692 that he had occasion to visit Bristol, where—according to a local tradition—he lay *perdu* for fear of bailiff all the week, but emerged in gorgeous raiment on Sunday, whence he was known by the nickname of “the Sunday gentleman.”

It was not as a business man that Defoe was to make his mark, though his business experiences coloured to some extent the literary productions to which he owes his fame. The course of his life was determined about the middle of the reign of William III by his introduction (we know not how) to William himself and to other influential persons. He frequently boasts of his personal intimacy with the “glorious and immortal” king (epithets, by the way, to the invention of which he has considerable claim), and in 1695 he was appointed accountant to the commissioners of the glass duty, which office he held for four years. During this time he produced (January 1698) his *Essay on Projects*, one of the first and not the least noteworthy of his works. This essay contains suggestions on banks, road-management, friendly and insurance societies of various kinds, idiot asylums, bankruptcy, academies (in the French sense),

military colleges, high schools for women, &c. It displays Defoe's lively and lucid style in full vigour, and abounds with ingenious thoughts and apt illustrations, though it illustrates also the unsystematic character of his mind. In the same year Defoe wrote the first of a long series of pamphlets on the then burning question of occasional conformity. In this, for the first time, he showed the unlucky independence which, in so many other instances, united all parties against him. On the one hand he pointed out to the dissenters the scandalous inconsistency of their playing fast and loose with sacred things, and on the other he denounced the impropriety of requiring tests at all. In direct support of the Government he published, towards the close of the reign, a *Defence of Standing Armies*, against Trenchard, and a set of pamphlets on the Partition Treaty. Thus in political matters he had the same fate as in ecclesiastical; for the Whigs were no more prepared than the Tories to support William through thick and thin. He also dealt with the questions of stock-jobbing and of electioneering corruption. But his most remarkable publication at this time—the publication, indeed, as the author of which he became famous—was *The True-Born Englishman*, a satire in rough but extremely vigorous verse on the national objection to William as a foreigner, and on the claim of purity of blood for a nation which Defoe chooses to represent as crossed and dashed with all the strains and races in Europe. He also took a prominent part in the proceedings which followed the famous Kentish petition, and was the author, and some say the presenter, of the equally famous *Legion Memorial*, which asserted in the strongest terms the supremacy of the electors over the elected, and of which even an irate House of Commons did not dare to take any great notice. The theory of the indefensible supremacy of the freeholders of England, whose delegates merely (according to this theory) the Commons were, was one of Defoe's favourite political tenets, and he returned to it in a most powerfully written tract entitled *The Original Power of the Collective Body of the People of England examined and asserted*. At the same time he was occupied in a controversy on the conformity question with the well-known John How (usually spelt Howe at present), and wrote several minor political tracts.

The death of William was a great misfortune to Defoe, and he soon felt the power of his adversaries. After publishing *The Mock Monarchs*, intended to satirize and rebuke the outbreak of Jacobite joy at the king's death, he turned his attention once more to ecclesiastical subjects, and, in an evil hour for himself, wrote the famous *Shortest Way with the Dissenters*. The traditional criticism of this remarkable pamphlet is a most curious example of the way in which thoroughly inappropriate descriptions of books pass from mouth to mouth. Every commentator (with the single exception of Mr Chadwick) has dilated upon its "exquisite irony." Now, the fact of the matter is, that in *The Shortest Way* there is no irony at all, and, as Defoe's adversaries acutely remarked, irony would never have been pleaded had not the author got into trouble, when of course it suited him *faire jêche de tout bois*. The pamphlet is simply an exposition in the plainest and most forcible terms of the extreme "high-flying" position, and every line of it might have been endorsed, and was endorsed, by consistent high-churchmen. The author's object clearly was by this naked presentation to awaken the dissenters to a sense of their danger, and to startle moderate churchmen by showing them to what end their favourite doctrines necessarily led. For neither of these purposes was irony necessary, and irony, we repeat, there is none. If any lingering doubt from the consensus of authority on the other side remain, let the student read *The Shortest Way* and then turn to Swift's *Modest Proposal* or

his *Reasons against Abolishing the Church of England*. He will soon see the difference. Ironical or not, however, it was unlikely that the high-churchmen and their leader Nottingham (the Don Disual of Swift) would let such a performance pass unnoticed. The author was soon discovered, and, as he absconded, an advertisement was issued offering a reward for his apprehension, and giving us the only personal description we possess of him, as "a middle-sized spare man about forty years old, of a brown complexion and dark brown-coloured hair, but wears a wig; a hooked nose, a sharp chin, grey eyes, and a large mole near his mouth." In this conjuncture Defoe had really no friends, for the dissenters were as much alarmed at his book as the high-flyers were irritated. He surrendered, and his defence appears to have been injudiciously conducted; at any rate he was fined 200 marks, and condemned to be pilloried three times, to be imprisoned indefinitely, and to find sureties for his good behaviour during seven years. His sojourn in the pillory, however, was rather a triumph than a punishment, for the populace took his side, and his *Hymn to the Pillory*, which he soon after published, is one of the best of his poetical works. Unluckily for him his condemnation had the indirect effect of destroying his business. He remained in prison until August 1704, and then owed his release to the intercession of Harley, who represented his case to the queen, and obtained for him not only liberty but pecuniary relief and employment, which, of one kind or another, lasted until the termination of Anne's reign. Defoe was uniformly grateful to the minister, and his language respecting him is in curious variance with that generally used. There can be little doubt that, independently of gratitude, Harley's moderation in a time of the extreme party-insanity was no little recommendation to Defoe. During his imprisonment the latter was by no means idle. A spurious edition of his works having been issued, he himself produced a collection of twenty-two treatises, to which sometime afterwards he added a second group of eighteen more. He also wrote in prison many short pamphlets, chiefly controversial, published a curious work on the famous storm of November 26, 1703, and started perhaps the most remarkable of all his projects, *The Review*. This was a paper which was issued during the greater part of its life three times a week. It was entirely written by Defoe, and extends to eight complete volumes and some few score numbers of a second issue. He did not confine himself to news, but threw his writing into the form of something very like finished essays on questions of policy, trade, and domestic concerns, while he also introduced a so-called "Scandal Club," in which minor questions of manners and morals were treated in a way which undoubtedly suggested the *Tatlers* and *Spectators* which followed. It is probable that if the five points of bulk, rapidity of production, variety of matter, originality of design, and excellence of style are taken together, hardly any author can show a work of equal magnitude. It is unlucky that only one complete copy of the work is known to exist, and that is in a private library. After his release he went to Bury St Edmunds for change of air, though he did not interrupt either his *Review* or his occasional pamphlets. One of these, *Giving Alms no Charity, and Employing the Poor a Grievance to the Nation*, is for the time an extraordinarily far-sighted performance. It denounces on the one hand indiscriminate alms-giving, and on the other the folly of national work shops, the institution of which on a parochial system had been proposed by Sir Humphrey Mackworth.

In 1705 appeared *The Consolidator, or Memoirs of Go me plo Sundry Transactions from the World in the Moon*, a political satire which is supposed to have given some hints for *Gulliver*; and at the end of the year Defoe performed a secret mission (the first of several of the kind) for Harley.

that position with the somewhat similar *Roxana*. Both are triumphs of novel-writing. Both have subjects of a rather more than questionable character, but both display the remarkable art with which Defoe handles such subjects. It is not true, as is sometimes said, that the difference of the two is the difference between gross and polished vice. The real difference is much more one of morals than of manners. Moll is by no means of the lowest class. Notwithstanding the greater degradation into which she falls, and her originally dependent position, she has been well educated, and has consorted with persons of gentle birth. She displays throughout much greater real refinement of feeling than the more high-flying *Roxana*, and is at any rate flesh and blood, if the flesh be somewhat frail and the blood somewhat hot. Neither of the two heroines has any but the rudiments of a moral sense; but *Roxana*, both in her original transgression and in her subsequent conduct, is actuated merely by avarice and selfishness—vices which are peculiarly offensive in connection with her other failing, and which make her thoroughly repulsive. The art of both stories is great, and as regards the episode in *Roxana* of the daughter Susannah is consummate; but the transitions of the later plot are less natural than those in *Moll Flanders*. It is only fair to notice that while the latter, according to Defoe's more usual practice, is allowed to repent and end happily, *Roxana* is brought to complete misery; Defoe's morality, therefore, required more repulsiveness in one case than in the other. *The Journal of the Plague Year*, more usually called, from the title of the second edition, *A History of the Plague*, has perhaps lacked less of its due meed of admiration than any of its author's minor works. Here also the accuracy and apparent veracity of the details is so great that many persons have taken it for an authentic record, while others have contended for the existence of such a record as its basis. But it appears that here too the genius of Mrs. Veal's creator must, in the absence of all evidence to the contrary, be allowed sufficient for the task. *The History of Colonel Jack* is an unequal book. There is hardly in *Robinson Crusoe* a scene equal, and there is consequently not in English literature a scene superior, to that praised by Lamb, and extracted in Knight's *Half Hours with the Best Authors*,—the scene where the youthful pick-pocket first exercises his trade, and then for a time loses his ill-gotten (though for his part he knows not the meaning of the word ill-gotten) gain. But great part of the book, and especially the latter portion, is dull; and in fact it may be generally remarked of Defoe that the conclusions of his tales are not equal to the beginning, perhaps from the restless indefatigability with which he undertook one work almost before finishing another. *Roxana, or the Fortunate Mistress*, already commented on, appeared in 1724; and in the same year came forth the first volume of *A Tour through the whole Island of Great Britain*, which was completed in the two following years. Much of the information in this was derived from personal experience, for Defoe claims to have made many more tours and visits about England than those of which we have record; but the major part must necessarily have been dexterous compilation. In 1725 appeared *A New Voyage round the World*, apparently entirely due to the author's own fertile imagination and extensive reading. It is full of his peculiar verisimilitude, and has all the interest of Anson's or Dampier's voyages, together with a charm of style superior even to that of the latter, and far beyond anything which the *soi-disant* chaplain of the "Centurion" could attain to. The journey by land across South America is of especial interest, and forms an admirable pendant to the African travels in *Singleton*. In the same year Defoe wrote a curious little pamphlet entitled *Everybody's Business is*

Nobody's Business, or Private Abuses Public Grievances, exemplified in the Pride, Insolence, and Exorbitant Wages of our Women-Servants, Footmen, &c. This subject was a very favourite one with Defoe, and in the pamphlet he showed the immaturity of his political views by advocating legislative interference in these matters. Like all his work of this sort, however, it is extremely amusing reading. Towards the end of this same year *The Complete English Tradesman*, which may be supposed to sum up the experience of his business life, appeared, and its second volume followed two years afterwards. This book has been variously judged. It is generally and traditionally praised, but those who have read it will be more disposed to agree with Charles Lamb, who considers it "of a vile and debasing tendency," and thinks it "almost impossible to suppose the author in earnest." It is certainly clear to those who know it what our foreign critics mean by the reproach of "shop-keeping;" and the intolerable meanness advocated for the sake of the paltriest gain, the entire ignoring of any pursuit in life except money-getting, and the representation of the whole duty of man as consisting first in the attainment of a competent fortune, and next, when that fortune has been attained, in spending not more than half of it, are certainly repulsive enough. But there are no reasons for thinking the performance ironical or insincere, and it cannot be doubted that Defoe would have been honestly unable even to understand Lamb's indignation. In 1706 came forth *The Political History of the Devil*. This is a curious book, partly explanatory of Defoe's ideas on morality, and partly belonging to a series of demonological works which he wrote, and of which the chief others are *A System of Magic*, and *An Essay on the History of Apparitions*. In all these works his treatment is on the whole rational and sensible; but in *The History of the Devil* he is somewhat hampered by an insufficiently worked out theory as to the nature and personal existence of his hero, and the manner in which he handles the subject is an odd and not altogether satisfactory mixture of irony and earnestness. There are many very amusing things in the book, but to speak of its "extraordinary brilliancy and wit" (as Mr H. Kingsley has done) is certainly inappropriate. The works which have just been mentioned, together with *A Plan of English Commerce*, containing very enlightened views on export trade, appeared in 1727-8. During the whole of the years from 1715 to 1728 Defoe had issued pamphlets and minor works far too numerous to mention. The only one of them perhaps which requires special notice is *Religious Courtship* (1722), a curious series of dialogues displaying Defoe's unaffected religiosity, and at the same time the rather meddling intrusiveness with which he applied his religious notions. This latter point was more flagrantly illustrated in one of his latest works, *The Treatise concerning the Use and Abuse of the Marriage Bed* (1727). This, which was originally issued with a much more offensive name, has been called "an excellent book with an improper title." It might more properly be called an ill-judged work, with a title which gives fair warning of its contents. *The Memoirs of Captain Carleton* (1728) have been long attributed to Defoe. There is, however, a well-known anecdote of Johnson which makes this extremely unlikely; it is now known that an actual officer of the name did exist and serve; and the internal evidence is, we think, strongly against Defoe's authorship. These *Memoirs* have been also attributed to Swift, with greater probability as far as style is concerned. *The Life of Mother Ross*, reprinted in Bohn's edition of Defoe, has no claim whatever to be considered his.

There is little to be said of Defoe's private life during this period. He must in some way or other have obtained a considerable income. In 1724 he had built himself a large

house at Stoke Newington (only pulled down about ten years ago), which had stables and grounds of considerable size. From the negotiations for the marriage of his daughter Sophia it appears that he had landed property in more than one place, and he had obtained on lease in 1722 a considerable estate from the corporation of Colchester. It was formerly thought that he soon got rid of this lease, but from documents in Mr Lee's possession it seems that he only effected a mortgage upon it (afterwards paid off), and that it was settled on his unmarried daughter at his death. Other property was similarly allotted to his widow and remaining children, though some difficulty seems to have arisen from the misconduct of his son, to whom, for some purpose, the property was assigned during his father's lifetime, and who refused to pay what was due. There is a good deal of mystery about the end of Defoe's life; it used to be said that he died insolvent, and that he had been in jail shortly before his death. As a matter of fact, after great suffering from gout and stone, he died of a lethargy in Ropemaker's Alley, Moorfields, on Monday the 6th of April 1731, and was buried in the well-known ground of Bunhill Fields. He left no will, all his property having been previously assigned, and letters of administration were taken out by a creditor. How his affairs fell into this condition, why he did not die in his own house, and why in the previous summer he had been in hiding, as we know he was from a letter still extant, are points apparently not to be cleared up.

Defoe was twice married, and his second wife Susannah outlived him a few months. He had seven children, one of whom, Martha, died in 1707—the others survived him. The eldest, Daniel, emigrated to Carolina. The second, Bernard or Benjamin Norton, has, like his father, a scandalous niche in the *Dunciad*. Three of the daughters, Maria, Henrietta, and Sophia, married well—the husband of the last-named being a Mr Henry Baker, of some repute in natural science. In April 1877 public attention was called to the existence, in some distress, of three maiden ladies, directly descended from Defoe, and bearing his name, and a crown pension of £75 a year was bestowed on each of them. There are several portraits of Defoe, the principal one being engraved by Vandergucht.

We have said that in his life-time Defoe, as not belonging to either of the great parties at a time of the bitterest party strife, was subjected to obloquy on both sides. The great Whig writers leave him unnoticed. Swift and Gay speak slightly of him,—the former, it is true, at a time when he was only known as a party pamphleteer. Pope, with less excuse, put him in the *Dunciad* towards the end of his life, but he confessed to Spence in private that Defoe had written many things and none bad. At a later period he was unjustly described as "a scurrilous party writer," which he certainly was not; but, on the other hand, Johnson spoke of his writing "so variously and so well," and put *Robinson Crusoe* among the only three books that readers wish longer. From Scott downwards the tendency to judge literary work on its own merits has to a great extent restored Defoe to his proper place, or, to speak more correctly, has set him there for the first time. Lord Macaulay's description of *Roxana*, *Moll Flanders*, and *Colonel Jack* as "utterly nauseous and wretched" must be set aside as a freak of criticism.

The grounds upon which the last-mentioned writer bases his depreciation of others of Defoe's minor works are curious. "He had undoubtedly a knack of making fiction look like truth, but is such a knack much to be desired? Is it not of the same sort as the knack of a painter who takes in the birds with his fruit?" And De Quincey regards the literary skill of writers of this class as comparatively inferior because of the close resemblance of their writings to the current speech and manner of their day. But

nothing is really a greater triumph of art than this similarity, and Macaulay has certainly made a mistake in confounding the requirements of painting and of writing. Scott justly observed that Defoe's style "is the last which should be attempted by a writer of inferior genius; for though it be possible to disguise mediocrity by fine writing, it appears in all its naked inanity when it assumes the garb of simplicity." The methods by which Defoe attains his result are not difficult to disengage. They are the presentment of all his ideas and scenes in the plainest and most direct language, the frequent employment of colloquial forms of speech, the constant insertion of little material details and illustrations, often of a more or less digressive form, and, in his historico-fictional works, as well as in his novels, the most rigid attention to vivacity and consistency of character. Plot he disregards, and he is fond of throwing his dialogues into regular dramatic form, with bye-play prescribed and stage directions interspersed. A particular trick of his is also to divide his arguments after the manner of the preachers of his day into heads and subheads, with actual numerical signs affixed to them. These mannerisms undoubtedly help and emphasize the extraordinary faithfulness to nature of his fictions, but it would be a great mistake to suppose that they fully explain their charm. Defoe possessed genius, and his secret is at the last as impalpable as the secret of genius always is.

The character of Defoe, both mental and moral, is very clearly indicated in his works. He, the satirist of the true-born Englishman, was himself a model, with some notable variations and improvements, of the Englishman of his period. He saw a great many things, and what he did see he saw clearly. But there were also a great many things which he did not see, and there was often no logical connection whatever between his vision and his blindness. The most curious example of this inconsistency, or rather of this indifference to general principle, occurs in his *Essay on Projects*. He there speaks very briefly and slightly of life-insurance, probably because it was then regarded as impious by religionists of his complexion. But on either side of this refusal are to be found elaborate projects of friendly societies and widows' funds, which practically cover, in a clumsy and roundabout manner, the whole ground of life-insurance. In morals it is evident that he was, according to his lights, a strictly honest and honourable man. But sentiment of any high-flying description (to use the cant word of his time) was quite incomprehensible to him, or rather never presented itself as a thing to be comprehended. He tells us with honest and simple pride that when his patron Harley fell out, and Godolphin came in, he for three years held no communication with the former, and seems quite incapable of comprehending the delicacy which would have obliged him to follow Harley's fallen fortunes. His very anomalous position in regard to Mist is also indicative of a rather blunt moral perception. One of the most affecting things in his novels is the heroic constancy and fidelity of the maid Amy to her exemplary mistress Roxana. But Amy, scarcely by her own fault, is drawn into certain breaches of certain definite moral laws which Defoe did not understand, and she is therefore condemned, with hardly a word of pity, to a miserable end. Nothing heroic or romantic was within Defoe's view; he could not understand passionate love, ideal loyalty, æsthetic admiration, or anything of the kind, and it is probable that many of the little sordid touches which delight us by their apparent satire were, as designed, not satire at all, but merely a faithful representation of the feelings and ideas of the classes of which he himself was a unit. We have noticed Charles Lamb's difficulty as to *The Complete Tradesman*, and we think that the explanation we have preferred will extend to a great deal more of his work.

Some peculiarities of that work follow as a natural corollary from those considerations. His political and economical pamphlets are almost unmatched as clear presentations of the views of their writer. For driving the nail home no one but Swift excels him, and Swift perhaps only in *The Drapier's Letters*. There is often a great deal to be said against the view presented in those pamphlets, but Defoe sees nothing of it. He was perfectly fair but perfectly one-sided, being generally happily ignorant of everything which told against his own view.

The same characteristics are curiously illustrated in his moral works. The morality of these is almost amusing in its downright positive character. With all the Puritan eagerness to push a clear, uncompromising, Scripture-based distinction of right and wrong into the affairs of every-day life, he has a thoroughly English horror of casuistry, and his clumsy canons consequently make wild work with the infinite intricacies of human nature. We have noticed, in remarking on *The Use and Abuse*, the worst instance of this blundering morality. Another, though very different instance, is his amusingly feminine indignation at the increased wages and embellished dress of servants. He is, in fact, an inaccurate instance of the tendency, which has so often been remarked by other nations in the English, to drag in moral distinctions at every turn, and to confound everything which is novel to the experience, unpleasant to the taste, and incomprehensible to the understanding, under the general epithets of wrong, wicked, and shocking. His works of this class therefore are now the least valuable, though not the least curious, of his books. His periodical publications necessarily fall to some extent under the two foregoing heads, and only deserve separate notice because of the novelty and importance of their conception. His poetry, as poetry, is altogether beneath criticism. It is sometimes vigorous, but its vigour is merely that of prose. Of his novels we have already spoken in detail, excepting, as universally known, *Robinson Crusoe*.

The earliest regular life and estimate of Defoe is that of Dr Towers in the *Biographia Britannica*. Chalmers's *Life*, however (1786), added very considerable information. In 1838 Mr Walter Wilson wrote the book which is the standard on the subject. It is coloured by political prejudice; it does not display any critical power of a high order; and it is in many parts rather a history of England with some relation to Defoe than a life of the latter; but it is a model of painstaking care, and by its abundant citations from works both of Defoe and of others, which are practically inaccessible to the general reader, is invaluable. In 1859 appeared a life of Defoe by Mr William Chadwick, an extraordinary rhapsody in a style which is half Cobbett and half Carlyle, but amusing, and by no means devoid of acuteness. In 1864 the discovery of the six letters stirred up Mr William Lee to a new investigation, and the results of this were published (London, 1869) in three large volumes. The first of these (well illustrated) contains a new life and particulars of the author's discoveries. The second and third contain fugitive writings assigned by Mr Lee to Defoe for the first time. For most of these, however, we have no authority but Mr Lee's own impressions of style, &c.; and consequently, though qualified judges will in most cases agree that Defoe may have written them, it cannot positively be stated that he did. Mr Lee is equally chary of his reasons for attributing and denying many larger works to his author. His work, though full of research and in many ways useful in correcting and enlarging previous accounts of Defoe, has therefore to be used with some caution. Besides these publications devoted exclusively to Defoe, there are others of the essay kind which may be consulted respecting him. Such articles have been written by Scott, Hazlitt, Forster, a writer in *The Retrospective Review*, Mr Leslie Stephen, and others. No criticism can, however, compare with three short pieces by Charles Lamb, two of which were written for Wilson's book, and the third for *The Reflector*.

It has been a frequent and well-grounded complaint that no complete edition of Defoe's works has ever been published. There is, as may be gathered from what has already been said, considerable uncertainty about many of them; and even if all contested works be excluded, the number is still enormous. Besides the list in Bohn's *Library*, which is somewhat of an *omnium gatherum*, three lists drawn with more or less

care have been compiled in the last half century. Wilson's contains 210 distinct works, three or four only of which are marked as doubtful; Hazlitt's enumerates 183 "genuine" and 52 "attributed" pieces, with notes on most of them; Mr Lee's extends to 254, of which 64 claim to be new additions. Of these large numbers many are in the original editions, extremely scarce, if not unique. Only one perfect copy of the *Review* is known to exist, and this, as well as the partially printed but never published *Complete Gentleman*, is in the hands of Mr James Crossley of Manchester, whose Defoe collection is nearest to completeness. Of reprints only one has ever aspired to be exhaustive. This was edited for the "Pulteney Library" by Hazlitt in 1840-43. It contains a good and full life mainly derived from Wilson, the whole of the novels (including the *Serious Reflections* now hardly ever published with *Robinson Crusoe*), *Jure Divino*, *The Use and Abuse of Marriage*, and many of the more important tracts and smaller works. The introductions are not written on a very uniform principle, but it is otherwise an excellent edition, and had it been continued (it stopped abruptly after the third volume had been completed and a few parts of a fourth issued) would have been satisfactory enough. It is still far the best, but is unfortunately scarce and expensive. There is also an edition, often called Scott's, but really edited by Sir G C Lewis, in twenty volumes (London, 1841). This contains the *Complete Tradesman*, *Religious Courtship*, *The Consolidator*, and other works not comprised in Hazlitt's, but is correspondingly deficient. It also is somewhat expensive in a complete state, and the editions chosen for reprinting are not always the best. Scott had previously in 1809 edited for Ballantyne some of the novels, in 12 vols. Bohn's libraries contain an edition which through want of support was stopped at the seventh volume. It includes the novels (except the third part of *Robinson Crusoe*), *The History of the Devil*, *The Storm*, and a few political pamphlets, also the undoubtedly spurious *Mother Ross*. In 1870 Mr Nimmo of Edinburgh published in one volume an admirable selection from Defoe. It contains Chalmers's *Life*, annotated and completed from Wilson and Lee, *Robinson Crusoe*, pts 1 and 2, *Colonel Jack*, *The Cavalier*, *Duncan Campbell*, *The Plague*, *Everybody's Business*, *Mrs Veal*, *The Shortest Way with Dissenters*, *Giving Alms no Charity*, *The True-born Englishman*, *Hymn to the Pillory*, and very copious extracts from *The Complete English Tradesman*. Had the space occupied by *Robinson Crusoe*, which in one form or another every one possesses, been devoted to a further selection from the minor works, this book would have gone far to supply a very fair idea of Defoe to all but professed students of literature. If we turn to separate works, the bibliography of Defoe is practically confined (except as far as original editions are concerned) to *Robinson Crusoe*. *Mrs Veal* has been to some extent popularized by the work which it helped to sell; *Religious Courtship* and *The Family Instructor* had a vogue among the middle class until well into this century, and *The History of the Union* was republished in 1786. But the reprints and editions of *Crusoe* have been innumerable, it has been often translated; and the eulogy pronounced on it by Rousseau gave it special currency in France, where imitations (or rather adaptations) have also been common. (G SA.)

DE GÉRANDO, MARIE JOSEPH (1772-1842), one of the most distinguished ethical and metaphysical philosophers of France, was born at Lyons, February 29, 1772. When that city was besieged in 1793 by the armies of the republic, the young De Gérando took up arms in defence of his native place, was made prisoner, and with difficulty escaped with his life. He first took refuge in Switzerland, whence he afterwards fled to Naples. In 1796, after an exile of three years, the establishment of the Directory allowed him to return to France. Finding himself, at the age of twenty-five, without a profession, he resolved to embrace the career of arms, and enlisted as a private in a cavalry regiment. About this time the Institute had proposed as a subject for an essay this question,—"What is the influence of symbols on the faculty of thought?" De Gérando gained the prize, and heard of his success after the battle of Zurich, in which he had distinguished himself. This literary triumph was the first step in his upward career. In 1799 he was attached to the ministry of the interior by Lucien Bonaparte; in 1804 he became general secretary under Champagny; in 1805 he accompanied Napoleon into Italy; in 1808 he was nominated master of requests; in 1811 he received the title of councillor of state; and in the following year he was appointed governor of Catalonia. On the overthrow of the empire, De Gérando

was allowed to retain this office; but having been sent during the hundred days into the department of the Moselle to organize the defence of that district, he was punished at the second Restoration by a few months of neglect. He was soon after, however, readmitted into the council of state, where he distinguished himself by the prudence and conciliatory tendency of his views. In 1819 he opened at the law-school of Paris a class of public and administrative law, which in 1822 was suppressed by Government, but was re-opened six years later under the Martignac ministry. In 1837 the Government acknowledged the long and important services which De Gérando had rendered to his country by raising him to the peerage. He died in Paris, November 9, 1842, at the age of seventy.

De Gérando's works are very numerous. That by which he is best known now, and which constitutes his chief title to posthumous fame, is his *Histoire Comparée des Systèmes de Philosophie relativement aux principes des Connaissances Humaines*, of which the first edition appeared at Paris in 1804, in 3 vols 8vo. The germ of this work had already appeared in the author's *Mémoire de la Génération des Connaissances Humaines*, crowned by the Academy of Berlin, and published at Berlin in 1802. In this work De Gérando, after a rapid review of ancient and modern speculations on the origin of our ideas, singles out the theory of primary ideas, which he endeavours to combat under all its forms. The latter half of the work, devoted to the analysis of the intellectual faculties, is intended to show how all human knowledge is the result of experience; and reflection is assumed as the source of our ideas of substance, of unity, and of identity.

De Gérando's great work is divided into two parts, the first of which is purely historical, and devoted to an exposition of various philosophical systems; in the second, which comprises fourteen chapters of the entire work, the distinctive characters and value of these systems are compared and discussed. Great fault has been found with this plan, and justly, as it is impossible to separate advantageously the history and critical examination of any doctrine in the arbitrary manner which De Gérando has chosen for himself. Despite this disadvantage, however, the work has great merits. It brought back the minds of men to a due veneration for the great names in philosophical science,—a point which had been utterly neglected by Condillac and his school. In correctness of detail and comprehensiveness of view it was greatly superior to every work of the same kind that had hitherto appeared in France. During the Empire and the first years of the Restoration, De Gérando found time, despite his political avocations, to recast the first edition of his *Histoire Comparée*, of which a second edition appeared at Paris in 1823, in 4 vols. 8vo. The plan and method of this edition are the same as in the first, but it is enriched with so many additions that it may pass for an entirely new work. The last chapter of the part published during the author's lifetime ends with the revival of letters and the philosophy of the 15th century. The second part, carrying the work down to the close of the 18th century, was published posthumously by his son in four vols (Paris, 1847). Twenty-three chapters of this had been left complete by the author in manuscript; the remaining three were supplied from other sources, chiefly printed but unpublished memoirs.

The next valuable work of De Gérando was his essay *Du perfectionnement moral et l'éducation de soi-même*, crowned by the French Academy in 1825. The fundamental idea of this work is that human life is in reality only a great education, of which perfection is the aim.

Besides the works already mentioned, De Gérando left many others, of which we may indicate the following:—*Considérations sur diverses méthodes d'observation des peuples sauvages*, 8vo, Paris, 1801;

Éloge de Dumarsais,—discours qui a remporté le prix proposé par la seconde classe de l'Institut National, 8vo, Paris, 1805; *Le Vainqueur du pauvre*, 8vo, Paris, 1820; *Institutes du Droit Administratif*, 4 vols. 8vo, Paris, 1830; *Cours normal des instituteurs primaires ou Directions relatives à l'éducation physique, morale, et intellectuelle dans les écoles primaires*, 8vo, Paris, 1832; *De l'éducation des Sourds-Muets*, 2 vols Paris, 1832; *De la Bienfaisance publique*, 4 vols. 8vo, 1833. A detailed analysis of the *Histoire Comparée des Systèmes* will be found in the *Fragments Philosophiques* of M. Cousin.

DEGGENDORF, or DECKENDORF, the chief town of a district in Lower Bavaria, about 25 miles north-west of Passau, on the left bank of the Danube, which is there crossed by two iron bridges. It is situated at the lower end of the beautiful valley of the Perlach, with the mountains of the Bavarian Forest rising behind, and in itself it is a well-built and attractive town. Besides the administrative offices it possesses an old council-house dating from 1566, a hospital, a lunatic asylum, an orphanage, a poor-house, and a large parish church rebuilt in 1756; but of greater interest than any of these is the Church of the Sacred Tomb, which for centuries attracted thousands of pilgrims to its *Porta Cæli*, *Gnadenpforte*, or Gate of Mercy, opened annually on St Michael's Eve, near the end of September, and closed again on the 4th of October. In 1837, on the celebration of the 500th anniversary of this solemnity, the number of pilgrims was reckoned at nearly 100,000. Such importance as the town possesses is now rather commercial than religious,—it being the main dépôt for the timber-trade of the Bavarian Forest, a station for the Danube steamboat company, and the seat of several mills, breweries, potteries, and other industrial establishments. On the bank of the Danube, outside the town, are the remains of the castle of Findelstein; and on the Geiersberg, in the immediate vicinity, stands the old pilgrimage-church of *Maria Dolores*. About six miles to the north is the village of Metten, with the Benedictine monastery founded by Charlemagne in 801, restored as an abbey in 1840 by Louis I. of Bavaria, and well-known for its educational institutions. The first mention of Deggenndorf occurs in 868, and it appears as a town in 1212. Henry XIII. of the Landslut dynasty made it the seat of a custom-house; and in 1331 it became the residence of Henry III. of Nattenberg, so called from a castle in the neighbourhood. In 1337 there took place in the town a dreadful massacre of the Jews, who were accused of having thrown the sacred host of the Church of the Sacred Tomb into a well; and it is probably from about this date that the pilgrimage above mentioned came into vogue. The town was captured by the Swedish forces in 1633, and in the war of the Austrian succession it was more than once laid in ashes. Population in 1871, 5452.

DEHRA DÚN, a district of British India in the Meerut (Mirat) division of the lieutenant-governorship of the North-Western Provinces, lies between 29° 57' and 30° 59' N. lat., and 77° 37' 15" and 78° 22' 45" E. long. It comprises the valley (*dún*) of Dehra, together with the hills division (*jargand*) of Jannsar Bawar, which runs from S.E. to N.W. of it, on the north. The district is bounded on the N. by the native state of Tehri or Garhwal, on the E. by British Garhwal, on the S. by the Siwálík hills, which separate it from Saháranpur district, and on the W. by the hill states of Simmr, Jubol, and Taráneh. The valley (*the Dún*) has an area of about 673 square miles, and forms a parallelogram 45 miles from N.W. to S.E. and 15 miles broad. It is well wooded, undulating, and intersected by streams. On the N.E. the horizon is bounded by the Mussooree (Mansúri) or lower range of the Himálayas, and on the S. by the Siwálík hills. The Himálayas in the north

of the district attain a height of between 7000 and 8000 feet, one peak reaching an elevation of 8565 feet; the highest point of the Siwālk range is 3041 above sea-level. The principal passes through the Siwālk hills are the Tūh pass, leading to the military station of Chakráta, and the Mohand pass leading to the sanatoriums of Mussooree and Landaur. The Ganges bounds the Dehra valley on the E.; the Jumna bounds it on the W. From a point about midway between the two rivers, and near the town of Dehra, runs a ridge which forms the watershed of the valley. To the west of this ridge, the water collects to form the Asan, a tributary of the Jumna; whilst to the east the Snsa receives the drainage and flows into the Ganges. To the east the valley is characterized by swamps and forests, but to the west the natural depressions freely carry off the surface drainage. Along the central ridge, the water-level lies at a great depth from the surface (228 feet), but it rises gradually as the country declines towards the great rivers. To meet the demand for water five canals have been constructed, and are fed by the hill streams. These canals have a total length of 67 miles, irrigate about 10,734 acres, and yield a net annual revenue of about £2300. Jaunsár Bāwar, north of the valley, comprises a triangular hilly tract, situated between the Tons and Jumna rivers near their point of confluence, and has an area of about 343 square miles. It is covered with forests of deodars, firs, cypresses, and oaks.

The agricultural products consist of rice, *mandua* (*Eleusine corocana*), oil seeds, millets, vegetables, and garden crops, such as potatoes, turmeric, red pepper, &c. The method of cultivation in the valley does not differ from that adopted in the plains; but in Jaunsár, the *khil* or *jum* system of cultivation is largely practised. This consists in clearing and burning the undergrowth on the steep banks of ravines and hills, and in sprinkling the seed, chiefly millets, over the ashes. The process yields a good crop for about two years, when the site is abandoned. The principal industries are tea planting and cultivation, rhea cultivation, and recently silk cultivation. The area under tea in 1872 was 2024 acres, yielding an out-turn of 297,828 lb, valued at £17,486.

The total revenue derived from Dehra district (exclusive of forests) in 1872-73 amounted to £19,169. Since 1872 the Dehra valley has been subject to the ordinary laws of other settled districts; but in the hilly division of Jaunsár a less formal code is better suited to the people, and this tract is still "non-regulation." The fiscal arrangements of Jaunsár are also peculiar. The tract is divided into *khats*, each presided over by a *sayana*, or head-man. The *sayanas* engage with the Government for the payment of the land revenue, and exercise police and civil jurisdiction in their respective *khats*; whilst a committee of *sayanas*, subject to the control of the British Superintendent of Dehra Dún, decide graver disputes affecting one or more *khats*. Education is progressing rapidly in the Dehra valley. Schools have also been established in Jaunsár. Mussooree has Protestant diocesan schools for European boys and girls; and similar institutions are managed by Roman Catholic priests for members of that faith. It likewise forms the head-quarters of an active American mission. There is little crime in the district, and in Jaunsár no regular police are found necessary.

The principal places in the district are Dehra, Mussooree, with the military sanatorium of Landaur, and the military station of Chakráta. Dehra town is the civil head-quarters of the district, and is constituted a municipality. It contained (1872) a total population of about 7000 souls, (5000 Hindus, and 2000 Mahometans). The municipal income is mainly derived from a house tax. Dehra is the head-quarters of the 2d Gurkha regiment, and of the Great

Trigonometrical Survey. The hill station of Mussooree is a favourite summer resort. Its population varies according to the season of the year. During the winter months it is almost entirely deserted. Landaur, the military depot for European convalescents, is really a portion of Mussooree. Chakráta is a hill station for a British regiment of infantry.

The census of 1872 returned the population of the entire district at 110,953 souls, of whom 102,814 were Hindus, 12,427 Mussulmans, 1061 Europeans, 191 Eurasians, and 460 native Christians. The Brahmins numbered 10,279, Rájpúts or military caste 33,125, Baniyás or traders 2664. The Brahmins and Rájpúts chiefly belong to the spurious hill clans bearing these names. The Mahometan population consists principally of Patháns and Sháikhs.

DEISM is the received name for a current of theological thought which, though not confined to one country, or to any well-defined period, had England for its principal source, and was most conspicuous in the last years of the 17th and the first half of the 18th century. The deists, differing widely in important matters of belief, were yet agreed in seeking above all to establish the certainty and sufficiency of natural religion in opposition to the positive religious, and in tacitly or expressly denying the unique significance of a supernatural revelation in the Old and New Testaments. They either ignored the Scriptures, endeavoured to prove them in the main but a helpful republication of the *Evangelium æternum*, or directly impugned their divine character, their infallibility, and the validity of their evidences as a complete manifestation of the will of God. The term deism is not only used to signify the main body of the deists' teaching, or the tendency they represent, but has of late especially come into use as a technical term for one specific metaphysical doctrine as to the relation of God to the universe, assumed to have been characteristic of the deists, and to have distinguished them from atheists, pantheists, and theists,—the belief, namely, that the first cause of the universe is a personal God, but is not only distinct from the world but apart from it and its concerns.

The words deism and deist were treated as novelties in the polemical theology of the latter half of the 16th century in France, but were used substantially in the same sense as they were a century later in England. By the majority of those historically known as the English Deists, from Blount onwards, the name was owned and honoured. They were also occasionally called *rationalists*. *Free-thinker* (in Germany, *Freidenker*) was generally taken to be synonymous with deist, though obviously capable of a wider signification, and as coincident with *esprit fort*, and with *libertin* in the original and theological sense of the latter word. *Naturalists* was a name frequently used of such as recognized no god but nature, of so-called Spinozists, atheists; but both in England and Germany, in the 18th century, this word was more commonly and aptly in use for those who founded their religion on the *lumen naturæ* alone. The same men were not seldom assailed under the name of *theists*, the later distinction between theist and deist, which stamped the latter word as excluding the belief in providence or in the immanence of God, was apparently formulated in the end of the 18th century by these rationalists who were aggrieved at being identified with the naturalists.

The chief names amongst the deists are those of Lord Herbert (1581-1648), Bleunt (1654-1693), Tindal (1657-1733), Woolston (1669-1733), Toland (1670-1722), Shaftesbury (1671-1713), Behngbroke (1678-1751), Collins (1676-1729), Morgan (1743), and Chubb (1679-1746). Annet, who died in 1768, and Dodwell who made his contribution to the controversy in 1742, are of less importance. Of the ten first named, nine appear to have been born within twenty-five years of one another; and it is noteworthy that by far the greater part of the

literary activity of the deists, as well as of their voluminous opponents, falls within the same half century.

The impulses that promoted a vein of thought cognate to deism were active both before and since the time of its greatest notoriety. But there are many reasons to show why, in the 17th century, men should have set themselves with a new zeal, in politics, law, and theology, to follow the light of nature alone, and to cast aside, to the utmost of their ability, the fetters of tradition and prescriptive right, of positive codes, and scholastic systems, and why in England especially there should, amongst numerous free-thinkers, have been not a few free writers. The significance of the Copernican system, as the total overthrow of the traditional conception of the universe, dawned on all educated men. In physics, Descartes had prepared the way for the final triumph of the mechanical explanation of the world in Newton's system. In England the new philosophy had broken with time-honoured beliefs more completely than it had done even in France; Hobbes was more startling than Bacon. Locke's philosophy, as well as his theology, served as a school for the deists. Men had become weary of Protestant scholasticism, religious wars had made peaceful thinkers seek to take the edge off dogmatical rancour; and the multiplicity of religious sects provoked distrust of the common basis on which all founded. There was a school of distinctively latitudinarian thought in the Church of England, others not unnaturally thought it better to extend the realm of the *adiaphora* beyond the sphere of Protestant ritual or the details of systematic divinity. Arminianism had revived the rational side of theological method. Semi-Arians and Unitarians, though sufficiently distinguished from the free-thinkers by reverence for the letter of Scripture, might be held to encourage departure from the ancient landmarks. The scholarly labours of Huet, Simon, Dupin, and Clericus, of Lightfoot, Spencer, and Prideaux, of Mill and Fell, furnished new materials for controversy; and the scope of Spinoza's *Tractatus Theologico-Politicus* had naturally been much more fully apprehended than ever his *Ethica* could be. The success of the English revolution permitted men to turn from the active side of political and theological controversy to speculation and theory; and curiosity was more powerful than faith. Much new ferment was working. The toleration and the free press of England gave it scope. Deism was one of the results.

A great part of the deistical teaching was the same from first to last; but though deism cannot be said to have any marked logical development, it went through a sufficiently observable chronological growth.

Long ere England was ripe to welcome deistic thought, Lord Herbert earned the name "Father of Deism" by laying down the main line of that religious philosophy which in various forms continued ever after to be the backbone of deistic systems. He based his theology on a comprehensive, if insufficient, survey of the nature, foundation, limits, and tests of human knowledge. And amongst the divinely implanted, original, indefeasible *notitiae communes* of the human mind, he found as foremost his five articles—that there is one supreme God, that he is to be worshipped, that worship consists chiefly of virtue and piety, that we must repent of our sins and cease from them, and that there are rewards and punishments here and hereafter. These truths, though often clouded, are found in all religions and at all times, and are the essentials of any religion—their universal prevalence being, along with their immediacy, an unmistakable mark of their verity. Thus Herbert sought to do for the religion of nature what his friend Grotius was doing for natural law,—making a new application of the standard of Vincentius, *Quod semper, quod ubique, quod ab omnibus*.

Herbert had hardly criticised the Christian revelation

either as a whole or in its details. Blount, a man of a very different spirit, did both, and in so doing may be regarded as having inaugurated the second main line of deistic procedure, that of historico-critical examination of the Old and New Testaments. Blount adopted and expanded Hobbes's arguments against the Mosaic authorship of the Pentateuch; and, mainly in the words of Burnet's *Archæologia Philosophica*, he asserts the total inconsistency of the Mosaic Hexaemeron with the Copernican theory of the heavens, dwelling with emphasis on the impossibility of admitting the view developed in Genesis, that the earth is the most important part of the universe. He assumes that the narrative was meant *ethically*, not *physically*, in order to eliminate false and polytheistic notions; and he draws attention to that double narrative in Genesis which was elsewhere to be so fruitfully handled. The examination of the miracles of Apollonius of Tyana, professedly founded on papers of Lord Herbert's, is meant to suggest similar considerations with regard to the miracles of Christ. Naturalistic explanations of some of these are proposed, and a mythical theory is distinctly foreshadowed when Blount dwells on the inevitable tendency of men, especially long after the event, to discover miracles attendant on the birth and death of their heroes. Blount assaults the doctrine of a mediator as irreligious; and much more pronouncedly than Herbert he dwells on the view, afterwards regarded as a special characteristic of all deists, that much or most error in religion has been invented or knowingly maintained by sagacious men for the easier maintenance of good government, or in the interests of themselves and their class. And when he heaps suspicion, not on Christian dogmas, but on beliefs of which the resemblance to Christian tenets is sufficiently patent, the real aim is so transparent that his method seems to partake rather of the nature of literary eccentricity than of polemical artifice; yet by this disingenuous indirectness he gave his argument that savour of duplicity which ever after clung to the popular conception of deism.

Shaftesbury, dealing with matters for the most part different from those usually handled by the deists, stands almost wholly out of their ranks. But he showed how loosely he held the views he did not go out of his way to attack, and made it plain how little weight the letter of Scripture had for himself; and, writing with much greater power than any of the deists, he was held to have done more than any one of them to forward the cause for which they wrought. Founding ethics on the native and cultivable capacity in men to appreciate worth in men and actions, and associating the apprehension of morality with the apprehension of beauty, he makes morality wholly independent of scriptural enactment, and still more, of the theological forecasting of future bliss or agony. He yet insisted on religion as the crown of virtue; and, arguing that religion is inseparable from a high and holy enthusiasm for the divine plan of the universe, he sought the root of religion in feeling, not in accurate beliefs or meritorious good works. The theology of those was of little account with him, he said, who in a system of dry and barren notions "pay handsome compliments to the Deity," "remove providence," "explode devotion," and leave but "little of zeal, affection, or warmth in what they call rational religion." In the protest against the scheme of "judging truth by counting noses," Shaftesbury recognized the danger of the standard which seemed to satisfy many deists; and in almost every respect he has more in common with those who afterwards, in Germany, annihilated the pretensions of complacent rationalism than with the rationalists themselves.

Toland, writing at first professedly without hostility to any of the received elements of the Christian faith, insisted that Christianity was not mysterious, and that the value of

religion could not lie in any unintelligible element; though we cannot know the real essence of God or of any of his creatures, yet our beliefs about God must be thoroughly consistent with reason. Afterwards, Toland discussed, with considerable real learning and much show of candour, the comparative evidence for the canonical and apocryphal Scriptures, and demanded a careful and complete historical examination of the grounds on which our acceptance of the New Testament canon rests. He contributed little to the solution of the problem, but forced the investigation of the canon alike on theologians and the reading public. Again, he sketched a view of early church history, further worked out by Semler, and surprisingly like that which, as elaborated by the Tübingen school, is still held with modifications by a large number of students of Christian antiquity. He tried to show, both from Scripture and extra-canonical literature, that the primitive church, so far from being an incorporate body of believers with the same creed and customs, really consisted of two schools, each possessing its "own gospel"—a school of Ebionites or Judaizing Christians, and the more liberal school of Paul. These parties, consciously but amicably differing in their whole relation to the Jewish law and the outside world, were subsequently forced into a non-natural uniformity. The cogency of Toland's arguments was weakened by his manifest love of paradox.

Collins, who had created much excitement by his *Discourse of Free-thinking*, insisting on the value and necessity of unprejudiced inquiry, published at a later stage of the deistic controversy the famous argument on the evidences of Christianity. Christianity is founded on Judaism; its main prop is the argument from the fulfilment of prophecy. Yet no interpretation or re-arrangement of the text of Old Testament prophecies will secure a fair and non-allegorical correspondence between these and their alleged fulfilment in the New Testament. The inference is not expressly drawn. Collins indicates the possible extent to which the Jews may have been indebted to Chaldeans and Egyptians for their theological views, especially as great part of the Old Testament would appear to have been re-modelled by Ezra; and, after dwelling on the points in which the prophecies attributed to Daniel differ from all other Old Testament predictions, he states the greater number of the arguments still used to show that the book of Daniel deals with events past and contemporaneous, and is from the pen of a writer of the Maccæan period.

Woolston, at first to all appearance working earnestly in behalf of an allegorical but believing interpretation of the New Testament miracles, ended by assaulting, with a yet unknown violence of speech, the absurdity of accepting them as actual historical events, and did his best to overthrow the credibility of Christ's principal miracles. The bitterness of his outspoken invective against the clergy, against all priestcraft and priesthood, was a new feature in deistic literature, and injured the author more than it furthered his cause.

Tindal's aim seems to have been a sober statement of the whole case in favour of natural religion, with copious but moderately worded criticism of such beliefs and usages in the Christian and other religions as he conceived to be either non-religious or directly immoral and unwholesome. The work in which he endeavoured to prove that true Christianity is as old as the creation, and is really but the republication of the gospel of nature, soon gained the name of the "Deist's Bible."

Morgan criticised with great freedom the moral character of the persons and events of Old Testament history, developing the theory of conscious "accommodation" on the part of the leaders of the Jewish church. This accommodation of truth, by altering the form and substance of it to meet the views and secure the favour of ignorant

and bigoted contemporaries, Morgan attributes also to the apostles and to Jesus. He likewise expands at great length a theory of the origin of the Catholic Church much like that sketched by Toland, but assumes that Paul and his party, latterly at least, were distinctly hostile to the Judaical party of their fellow-believers in Jesus as the Messiah, while the college of the original twelve apostles and their adherents viewed Paul and his followers with suspicion and disfavour. Persecution from without Morgan regards as the influence which mainly forced the antagonistic parties into the oneness of the catholic and orthodox church.

Annet made it his special work to invalidate belief in the resurrection of Christ, and to discredit the work of Paul.

Chubb, the least learnedly educated of the deists, did more than any of them, save Herbert, to round his system into a logical whole. From the New Testament he sought to show that the teaching of Christ substantially coincides with natural religion as he understood it. But his main contention is that Christianity is not a doctrine but a life, not the reception of a system of truths or facts, but a pious effort to live in accordance with God's will here, in the hope of joining him hereafter. Chubb dwells with special emphasis on the fact that Christ preached the gospel to the poor, and argues, as Tindal had done, that the gospel must therefore be accessible to all men without any need for learned study of evidences for miracles, and intelligible to the meanest capacity.

Dodwell's ingenious thesis, that Christianity is not founded on argument, was certainly not meant as an aid to faith; and, though its starting-point is different from all other deistical works, it may safely be reckoned amongst their number.

Though himself contemporary with the earlier deists, Bolingbroke's principal works were posthumously published after interest in the controversy had declined. His whole strain, in sharp contrast to that of most of his predecessors, is cynical and satirical, and suggests that most of the matters discussed were of small personal concern to himself. He gives fullest scope to the ungenerous view that a vast proportion of professedly revealed truth was ingeniously palmed off by the more cunning on the more ignorant for the convenience of keeping the latter under. But he writes with keenness and wit, and knows well how to use the materials already often taken advantage of by earlier deists.

In the substance of what they received as natural religion, the deists were for the most part agreed; Herbert's articles continued to contain the fundamentals of their theology. Religion, though not identified with morality, had its most important outcome in a faithful following of the eternal laws of morality, regarded as the will of God. With the virtuous life was further to be conjoined a humble disposition to adore the Creator, avoiding all factitious forms of worship as worse than useless. The small value attributed to all outward and special forms of service, and the want of any sympathetic craving for the communion of saints, saved the deists from attempting to found a free-thinking church, a creedless communion. They seem generally to have inclined to a quietistic accommodation to established forms of faith, till better times came. They steadfastly sought to eliminate the miraculous from theological belief, and to expel from the system of religious truth all debatable, difficult, or mysterious articles. They aimed at a rational and intelligible faith, professedly in order to make religion, in all its width and depth, the heritage of every man. They regarded with as much suspicion the notion of a "peculiar people" of God, as of a unique revelation, and insisted on the salvability of the heathen. They rejected the doctrine of the Trinity, and protested against mediatorship, atonement, and the imputed righteousness of Christ, always laying more stress on the teach-

ing of Christ than on the teaching of the church about him; but they repeatedly laid claim to the name of Christians or of Christian deists. Against superstition, fanaticism, and priestcraft they were incessantly lifting up their testimony. They all recognized the soul of man—not regarded as intellectual alone—as the ultimate court of appeal. But they varied much in their attitude towards the Bible. Some were content to argue their own ideas into Scripture, and those they disliked out of it; to one or two it seemed a satisfaction to discover difficulties in Scripture, to point to historical inaccuracies and moral defects. Probably Chubb's position on this head is most fairly characteristic of deism. He holds that the narrative, especially of the New Testament, is in the main accurate, but, as written after the events narrated, has left room for misunderstandings and mistakes. The apostles were good men, to whom, after Christ, we are most indebted; but they were fairly entitled to their own private opinions, and naturally introduced these into their writings. The epistles, according to Chubb, contain errors of fact, false interpretations of the Old Testament, and sometimes disfigurement of religious truth. Fortunately, however, the points on which the private opinions of apostolic men might naturally differ most widely, such as the doctrine of the Logos, are matters which have nothing to do with the salvation of souls.

The general tendency of the deistical writings is sufficiently self-consistent to justify a common name. But it is vain to speak of deism as a compact system, or to regard it as the outcome of any one line of philosophical thought. Of matters generally regarded as pertaining to natural religion, that on which they were least agreed was the certainty, philosophical demonstrability, and moral significance of the immortality of the soul, so that the deists have sometimes been grouped into "mortal" and "immortal" deists. For some the belief in future rewards and punishments was an essential of religion; some seem to have questioned the doctrine as a whole; and, while others made it a basis of morality, Shaftesbury protested against the ordinary theological form of the belief as immoral. No two thinkers could well be more opposed than Shaftesbury and Hobbes; yet sometimes ideas from both were combined by the same writer. Collins was a pronounced necessitarian, Morgan regarded the denial of free will as tantamount to atheism. And nothing can be more misleading than to assume that the belief in a Creator, existent wholly apart from the work of his hands, was characteristic of the deists as a body. In none of them is any theory on the subject specially prominent; save in their denial of miracles, of supernatural revelation, and a special redemptive interposition of God in history, they seem to have thought of providence much as the mass of their opponents did. Herbert starts his chief theological work with the design of vindicating God's providence. Shaftesbury vigorously protests against the notion of a wholly transcendent God. Morgan more than once expresses a theory that would now be pronounced one of immanence. Toland, the inventor of the name of pantheism, was notoriously, for a great part of his life, in some sort a pantheist. And while as thinkers they diverged in their opinions, so too the deists differed radically from one another in their character, in reverence for their subject, and in religious earnestness and moral worth.

The deists were not powerful writers; none of them was distinguished by wide and accurate scholarship; hardly any was either a deep or comprehensive thinker. But though they generally had the best scholarship of England against them, they were bold, acute, well-informed men, they appreciated more fully than their contemporaries not a few truths now all but universally accepted, and they

seemed therefore entitled to leave their mark on subsequent theological thought. Yet while the seed they sowed was taking deep root in France and in Germany, the English deists, the most notable men of their time, were soon forgotten, or at least ceased to be a prominent factor in the intellectual life of the century. The controversies they had provoked collapsed rather than were finally settled; and deism became a by-word even amongst those who were in no degree anxious to appear as champions of orthodoxy.

The fault was not wholly in the subjectivism of the movement. But the subjectivism that founded its theology on the "common sense" of the individual was accompanied by a fatal pseudo-universalism which, cutting away all that was peculiar, individual, and most intense in all religions, left in any one of them but a lifeless form. A theology consisting of a few vague generalities was sufficient to sustain the piety of the best of the deists; but it had not the concreteness or intensity necessary to take a firm hold on those whom it emancipated from the old beliefs. The negative side of deism came to the front, and, communicated with fatal facility, seems ultimately to have constituted the deism that was commonly professed at the clubs of the wits and the tea-tables of polite society. But the intenser religious life before which deism fell was also a revolt against the abstract and argumentative orthodoxy of the time.

That the deists appreciated fully the scope of difficulties in Christian theology and the sacred books is not their most noteworthy feature; but that they made a stand, sometimes cautiously, often with outspoken fearlessness, against the presupposition that the Bible is the religion of Protestants. They themselves gave way to another presupposition equally fatal to true historical research, though in great measure common to them and their opponents. It was assumed by deists in debating against the orthodox, as it is now by orthodox Protestants in contending against the Romish Church, that the flood of error in the hostile camp was due to the benevolent cunning or deliberate self-seeking of unscrupulous men, held to by the ignorant with the obstinacy of prejudice.

Yet deism deserves to be remembered as a strenuous protest against bibliolatry in every degree and against all traditionalism in theology. It sought to look not a few facts full in the face, from a new point of view and with a thoroughly modern, though unhistorical spirit. It was not a religious movement; and though, as a defiance of the accepted theology, its character was mainly theological, the deistical crusade belongs, not to the history of the church, or of dogma, but to the history of general culture. It was an attitude of mind, not a body of doctrine; its nearest parallel is probably to be found in the eclectic strivings of the Renaissance philosophy and the modernizing tendencies of eisalpine humanism. The controversy was assumed to be against prejudice, ignorance, obscurantism; what monks were to Erasmus the clergy as such were to Woolston. Yet English deism was in many ways characteristically English. The deists were, as usually happens with the leaders of English thought, no class of professional men, but represented every rank in the community. They made their appeal in the mother tongue to all men who could read and think, and sought to reduce the controversy to its most direct practical issue, making it turn as much as possible on hard facts or the data of common sense. And, with but one or two exceptions, they avoided wildness in their language as much as in the general scheme of theology they proposed. If at times they had recourse to ambiguity of speech and veiled polemic, this might be partly excused by the death of Aikinhead on the scaffold, and Woolston's imprisonment.

French deism, the direct progeny of the English movement, was equally short-lived. Voltaire was to the end a deist of the school of Bolingbroke; Rousseau could have claimed kindred with the nobler deists. Diderot was for a time heartily in sympathy with deistic thought, and the *Encyclopédie* was in its earlier portion an organ of deism. But as Locke's philosophy became in France sensationalism, and as Locke's pregnant question, reiterated by Collins, how we know that the divine power might not confer thought on matter, led the way to dogmatic materialism, so deism soon gave way to forms of thought more directly and extremely subversive of the traditional theology.

In Germany there was a native free-thinking theology nearly contemporary with that of England, whence it was greatly developed and supplemented. The compact rational philosophy of Wolff nourished a theological rationalism which in Germany was wholly undistinguishable from dogmatic deism; while, in the case of the historico-critical school to which Semler belonged, the distinction is not always easily drawn—although these rationalists professedly recognized in Scripture a real divine revelation, mingled with local and temporary elements. It deserves to be noted here that the former, the theology of the *Aufklärung*, was, like that of the deists, destined to a short-lived notoriety; whereas the solid, accurate, and scholarly researches of the rationalist critics of Germany, undertaken with no merely polemical spirit, not only form an epoch in the history of theology, but have taken a permanent place in the body of theological science. Ere *rationalismus vulgaris* fell before the combined assault of Schleiermacher's subjective theology and the deeper historical insight of the Hegelians, it had found a refuge successively in the Kantian postulates of the practical reason, and in the vague but earnest faith-philosophy of Jacobi.

In England, though the deists were forgotten, their spirit was not wholly dead. For men like Hume and Gibbon the standpoint of deism was long left behind, yet Gibbon's famous two chapters might well have been written by a deist. Even now, between scientific atheism and speculative agnosticism on the one hand and church orthodoxy on the other, many seem to cling to a theology nearly allied to deism. Rejecting miracles and denying the infallibility of Scripture, protesting against Calvinistic views of sovereign grace and having no interest in evangelical Arminianism, the faith of such inquirers seems fairly to coincide with that of the deists. Wherever religious indifferentism is rife, the less generous forms of deism are still alive. And even some cultured theologians, the historical representatives of latitudinarianism, seem to accept the great body of what was contended for by the deists, though they have a fuller appreciation of the power of spiritual truth, and a truer insight into the ways of God with man in the history of the world.

The deists displayed a singular incapacity to understand the true conditions of history; yet amongst them there were some who pointed the way to the truer, more generous interpretation of the past. When Shaftesbury wrote that "religion is still a discipline, and progress of the soul towards perfection," he gave birth to the same thought that was afterwards hailed in Lessing's *Erziehung des Menschengeschlechtes* as the dawn of a fuller and a purer light on the history of religion and on the development of the spiritual life of mankind.

DEJANIRA, the wife of Hercules. See HERCULES.

DEKKER, JEREMIAS DE (1610-1666), a Dutch poet, was born at Dort in 1610. He received his entire

education from his father, a native of Antwerp, who, having embraced the reformed religion, had been compelled to take refuge in Holland. Entering his father's business at an early age, he found leisure to cultivate his taste for literature and especially for poetry, and to acquire without assistance a competent knowledge of English, French, Latin, and Italian. His first poem was a paraphrase of the Lamentations of Jeremiah (*Klaaglieden van Jeremias*), which was followed by translations and imitations of Horace, Juvenal, and other Latin poets. The most important of his original poems were a collection of epigrams (*Punttdichten*) and a satire in praise of avarice (*Lof der Geldzucht*). The latter is his best known work. Written in a vein of light and yet effective irony, it is usually ranked by critics along with Erasmus's *Praise of Folly*. Dekker died at Amsterdam in November 1666. A complete collection of his poems, edited by Bronckus van Nideck, was published at Amsterdam in 1726 under the title *Exercices Poétiques* (2 vols 4to). Selections from his poems are included in Siegenbeek's *Proeven van nederduitsche Dichtkunde* (1823), and from his epigrams in Geysbeek's *Epigrammatische Anthologie*, 1827.

DEKKER, THOMAS, dramatist. It is impossible to make out, from the scanty records of Dekker's personal life, what manner of man he was. His name occurs frequently in Henslowe's *Diary* during the last year of the 16th century; he is mentioned there as receiving loans and payments for writing plays in conjunction with Ben Jonson, Chettle, Haughton, and Day, and he would appear to have been then in the most active employment as a playwright. The titles of the plays on which he was engaged from April 1599 to March 1599-1600 are *Troilus and Cressida*, *Orestes Furies*, *Agamemnon*, *The Stepmother's Tragedy*, *Beat a Brain*, *Page of Plymouth*, *Robert the Second*, *Patient Grissel*, *The Shoemaker's Holiday*, *Truth's Supplication to Candlelight*, *The Spanish Moor's Tragedy*, *The Seven Wise Masters*. At that date it is evident that Dekker's services were in great request for the stage. He is first mentioned in the *Diary* two years before, as having sold a book; the payments in 1599 are generally made in advance, "in earnest" of work to be done. In the case of three of the above plays, *Orestes Furies*, *Truth's Supplication*, and the *Shoemaker's Holiday*, Dekker is paid as the sole author. Only the *Shoemaker's Holiday* has been preserved; it was published in 1600. It would be unsafe to argue from the classical subjects of some of these plays that Dekker was then a young man from the university, who had come up like so many others to make a living by writing for the stage. Classical knowledge was then in the air; playwrights in want of a subject were content with translations, if they did not know the originals. However educated, Dekker was then a young man just out of his teens, if he spoke with any accuracy when he said that he was threescore in 1637; and it was not in scholarly themes that he was destined to find his true vein. The call for the publication of the *Shoemaker's Holiday*, which deals with the life of the city, showed him where his strength lay. To give a general idea of the substance of Dekker's plays, there is no better way than to call him the Dickens of the Elizabethan period. The two men were as unlike as possible in their habits of work, Dekker having apparently all the thriftlessness and impecunious shamelessness of Micawber himself. Dekker's Bohemianism appears in the slightness and hurry of his work, a strong contrast to the thoroughness and rich completeness of every labour to which Dickens applied himself; perhaps also in the exquisite freshness and sweetness of his songs, and the natural charm of stray touches of expression and description in his plays. But he was like Dickens in the bent of his genius towards the representation of the life around him in

London, as well as in the humorous kindliness of his way of looking at that life, his vein of sentiment, and his eye for odd characters. There is a passage in Ben Jonson's caricature of Dekker under the name of "Crispinus,"—an allusion to his *Shoemaker's Holiday*,—from which it would appear that Dekker prided himself on his powers of observation. The less is included in the greater; the random pickings of Dekker, hopping here and there in search of a subject, give less complete results than the more systematic labours of Dickens. Dekker's Simon Eyre, the good-hearted, mad shoemaker, and his Orlando Frisco-baldo, are touched with a kindly humor in which Dickens would have delighted, his Infelices, Fiamettas, Tormiellas, even his Bellafronta, have a certain likeness in type to the heroines of Dickens; and his roaring blades and their gulls are prototypes of Sir Mulberry Hawk and Lord Frederick Versopht. Only there is this great difference in the spirit of the two writers, that Dekker wrote without the smallest apparent wish to reform the life that he saw, desiring only to exhibit it, and that on the whole, apart from his dramatist's necessity of finding interesting matter, he cast his eye about rather with a liking for the discovery of good under unpromising appearances than with any determination to detect and expose vice. The observation must also be made that Dekker's personages have much more individual character, more of that mixture of good and evil which we find in real human beings. Hack-writer though Dekker was, and writing often under sore pressure, there is no dramatist whose personages have more of the breath of life in them, drawing with easy, unconstrained hand, he was a master of those touches by which an imaginary figure is brought home to us as a creature with human interests. A very large part of the motive power in his plays consists in the temporary yielding to an evil passion. The kindly philosophy that the best of natures may be for a time perverted by passionate desires is the chief animating principle of his comedy. He delights in showing women listening to temptation, and apparently yielding, but still retaining sufficient control over themselves to be capable of drawing back when on the verge of the precipice. The wives of the citizens were his heroines, pursued by the unlawful addresses of the gay young courtiers; and on the whole Dekker, from inclination apparently as well as policy, though himself, if Ben Jonson's satire had any point, a bit of a dandy in his youth, took the part of morality and the city, and either struck the rakes with remorse or made the objects of their machinations clever enough to outwit them. From Dekker's plays we get a very lively impression of all that was picturesque and theatrically interesting in the city life of the time, the interiors of the shops and the houses, the tastes of the citizens and their wives, the tavern and tobacco-shop manners of the youthful aristocracy and their satellites. The social student cannot afford to overlook Dekker; there is no other dramatist of that age from whom we can get such a vivid picture of contemporary manners in London. He drew direct from life, in so far as he idealized, he did so not in obedience to scholarly precepts or dogmatic theories, but in the immediate interests of good-natured farce and tender-hearted sentiment.

In all the serious parts of Dekker's plays there is a charming delicacy of touch, and his smallest scraps of song are bewitching; but his plays, as plays, owe much more to the interest of the characters and the incidents than to any excellence of construction. We see what use could be made of his materials by a stronger intellect in *Westward Ho!* which he wrote in conjunction with John Webster. The play, somehow, though the parts are more firmly knit together, and it has more unity of purpose, is not so interesting as Dekker's unaided work. Middleton formed a

more successful combination with Dekker than Webster; the *Honest Whore*, or the *Converted Courtesan*, is generally regarded as the best that bears Dekker's name, and in it he had the assistance of Middleton, although the assistance was so immaterial as not to be worth acknowledging in the title-page. Still that Middleton, a man of little genius but of much practical talent and robust humor, was serviceable to Dekker in determining the form of the play may well be believed. The two wrote another play in concert, the *Roaring Girl*, for which Middleton probably contributed a good deal of the matter, as well as a more symmetrical form than Dekker seems to have been capable of devising. In the *Witch of Edmonton*, except in a few scenes, it is difficult to trace the hand of Dekker with any certainty, his collaborateurs were John Ford and William Rowley; to Ford probably belongs the intense brooding and murderous wrath of the old hag, which are too direct and hard in their energy for Dekker, while Rowley may be supposed to be responsible for the delineation of country life.

When Langbaine wrote his *Account of the English Dramatic Poets* in 1691, he spoke of Dekker as being "more famous for the contention he had with Ben Jonson for the bays, than for any great reputation he had gained by his own writings." This is an opinion that could not be professed now, when Dekker's work is read. In the contention with Ben Jonson, one of the most celebrated quarrels of authors, the origin of which is matter of dispute, Dekker seems to have had very much the best of it. We can imagine that Jonson's attack was stinging at the time, because it seems to be full of sarcastic personalities, but it is dull enough now when nobody knows what Dekker was like, nor what was the character of his mother. There is nothing in the *Poetaster* that has any point as applied to Dekker's powers as a dramatist, while on the contrary the *Untrussing of the Humorous Poet* is full of pungent ridicule of Jonson's style, and of rebuffs and insults conceived in the happiest spirit of good-natured mockery. Dekker has been accused of poverty of invention in adopting the characters of the *Poetaster*, but it is of the very pith of the jest that Dekker should have set on Jonson's own foul-mouthed Captain Tucca to abuse Horace himself.

Dekker's plays were published in the following order—*The Shoemaker's Holiday*, 1600, *The Pleasant Comedy of old Fortunatus*, 1600, *Satiromastix*, 1602, *Patient Grissel* (in conjunction with Chettle and Haughton) 1603, *The Honest Whore* (Part 1.) 1604, *The Whore of Babylon*, 1607; *Westward Ho! Northward Ho!* and *Sir Thomas Wyatt* (in conjunction with Webster), 1607; *The Roaring Girl* (in conjunction with Middleton), 1611, *If it be not good, the Devil is in it*, 1612, *The Virgin Martyr* (in conjunction with Massinger), 1622, *Match Me in London*, 1631, *The Wonder of a Kingdom*, 1638, *The Sun's Darling* (not published till 1656), and *The Witch of Edmonton* (written in conjunction with Rowley and Ford), 1658. An edition of the collected dramatic works of Dekker is published by John Pearson. Some of his prose tracts, of which he wrote many, are reprinted by the Shakespeare Society, notably *The Seven Deadly Sins of London* and *The Gull's Hornbook*.

(W. M.)

DE LA BECHE, HENRY THOMAS (1796–1855), one of the band of enthusiastic workers by whom the science of geology was developed so rapidly in England during the early part of this century, was born in the year 1796. His father, an officer in the army, possessed landed property in Jamaica, but died while his son was still young. The boy accordingly spent his youth with his mother among the interesting and picturesque coast cliffs of the south-west of England, where probably he early imbibed that love for geological pursuits, and cultivated that marked artistic faculty, to which in large measure he owed the high position he ultimately reached. When fourteen years of age, being destined, like his friend Murchison, for the military profession, he entered the college at Great Marlowe, where he specially distinguished himself by the rapidity and skill with which he executed sketches showing the salient

features of a district. But this aptitude, which would have been of great service in a soldier's life, was not called forth for warlike purposes. The peace of 1815 changed the career of many young aspirants for military distinction, and among them De la Beche. Instead of pursuing the calling he had chosen, he began to devote himself with ever-increasing assiduity to the pursuit of geology. When only twenty-one years of age he joined the Geological Society of London, continuing throughout life to be one of its most active, useful, and honoured members. Possessing a fortune sufficient for the gratification of his tastes, he visited many localities of geological interest in Britain, and spent some time on the Continent studying features in the geology and physical geography of France and Switzerland. His journeys seldom failed to bear fruit in suggestive notes, papers, or sketches. Early attachment to the south-west of England led him back to that region, where, with augmented power from enlarged experience and reflection, he began the detailed investigation of the rocks of Cornwall and Devon. Thrown much into contact with the mining community of that part of the country, he conceived the idea that the nation ought to compile a geological map of the United Kingdom, and collect and preserve specimens to illustrate, and perhaps even to aid in further developing, its mineral industries. He showed his skilful management of affairs by inducing the Government of the day to recognize his work and give him an appointment in connection with the Ordnance Survey. This formed the starting-point of the present Geological Survey of Great Britain and Ireland. Year by year increasing stores of valuable specimens were transmitted to London; for De la Beche enlisted the sympathy and co-operation of the mining authorities of Cornwall and Devon. At last the building where the young Museum of Economic Geology was placed became too small. But De la Beche, having seen how fruitful his first idea had become, determined to use all his persuasion to prevail on the authorities not merely to provide a large structure, but to widen the whole scope of the scientific establishment of which he was the head, so as to impart to it the character of a great educational institution where practical as well as theoretical instruction should be given in every branch of science necessary for the conduct of mining work. In this endeavour he was again successful. Parliament sanctioned the creation of a museum in Jermyn Street, London, and the organization of a staff of professors with laboratories and other appliances. The establishment was opened in 1851. The Geological Survey also, which had grown up under his care, no longer under the Ordnance Department, received a new organization and an increase to its staff. To De la Beche belongs the high praise of having entirely originated and developed this important branch of the public service. Many foreign countries have since formed geological surveys avowedly based upon the organization and experience of that of the United Kingdom. The British colonies, also, have in many instances established similar surveys for the development of their mineral resources, and have had recourse to the parent survey for advice and for officers to conduct the operations.

De la Beche was an able mineralogist as well as an admirable field-geologist. He published numerous memoirs on English geology in the *Transactions of the Geological Society of London*, as well as in the *Memoirs of the Geological Survey of the United Kingdom*. He likewise wrote a valuable text-book of geology, and a work of singular breadth and clearness—*Researches in Theoretical Geology*—in which he enunciated a philosophical treatment of geological questions much in advance of his time. An early volume, *How to Observe in Geology*, was rewritten and enlarged by him late in life, and published under the title of *The Geological Observer*. It was marked by wide

practical experience, multifarious knowledge, philosophical insight, and a genius for artistic delineation of geological phenomena. He received from many foreign societies recognition of his services to science, and at the close of his life was awarded the Wollaston medal—the highest honour in the gift of the Geological Society of London. After a life of constant activity he began to suffer from partial paralysis, but, though becoming gradually worse, continued able to transact his official business until a few days before his death, which took place on 13th April 1855.

DELACROIX, FERDINAND VICTOR EUGÈNE, (1798–1863), a French painter of history, was born at Charenton-St-Maurice, near Paris, 26th April 1798. His father was a partisan of the most violent faction during the time of the Revolution. The family affairs seem to have been conducted in the wildest manner, and the accidents that befell the child, well authenticated as they are said to be, make it almost a miracle that he survived. He was first nearly burned to death in the cradle by a nurse falling asleep over a novel, and the candle dropping on the coverlet, this left permanent marks on his arms and face. He was next dropped into the sea by another *bonne*, who was climbing up a ship's side to see her lover. He was nearly poisoned, and nearly choked, and, to crown all, he tried to hang himself, without any thought of suicide, in imitation of a print exhibiting a man in that position of final ignominy. The prediction of a charlatan founded on his horoscope has been preserved:—"Cet enfant deviendra un homme célèbre, mais sa vie sera des plus laborieuses, des plus tourmentées, et toujours livrée à la contradiction."

Delacroix the elder died at Bordeaux when Eugene was seven years of age, and his mother returned to Paris and placed him in the Lycée Napoléon. Afterwards, on his determining to be a painter, he entered the *atelier* of Baron Guérin, who affected to treat him as an amateur. His fellow-pupil was Scheffer, who was alike by temperament and antecedents the opposite of the *bizarre* Delacroix, and the two remained antagonistic to the end of life. Delacroix's acknowledged power and yet want of success with artists and critics—Thiers being his only advocate—perhaps mainly resulted from his bravura and rude dash in the use of the brush, at a time when smooth roundness of surface was general. His first important picture, Dante and Virgil, was painted in his own studio, and when Guérin went to see it he flew into a passion, and told him his picture was absurd, detestable, exaggerated. "Why ask me to come and see this? you knew what I must say." Yet his work was received at the Salon, and produced an enthusiasm of debate (1822). Some said Géricault had worked on it, but all treated it with respect. Still in private his position, even after the larger tragic picture, the Massacre of Seign, had been deposited in the Luxembourg by the Government, became that of an Ishmaelite. The war for the freedom of Greece then going on moved him deeply, and his next two pictures—Marino Faliero Decapitated on the Giant's Staircase of the Ducal Palace (which has always remained a European success), and Greece Lamenting on the Ruins of Missolonghi—with many smaller works, were exhibited for the benefit of the patriots in 1826. This exhibition was much visited by the public, and next year he produced another of his important works, Sardanapalus, from Byron's drama. After this, he says, "I became the abomination of painting, I was refused water and salt,"—but, he adds with singularly happy naïveté, "J'étais enchanté de moi-même!" The patrimony he inherited, or, perhaps it should be said, what remained of it, was 10,000 *livres de rente*, and with economy he lived on this, and continued the expensive process of painting large historical pictures. In 1831 he reappeared in the Salon with six works, and immediately after left for Morocco, where

he found much congenial matter. Delacroix never went to Italy, he refused to go on principle, lest the old masters, either in spirit or manner, should impair his originality and self-dependence. His greatest admiration in literature was the poetry of Byron; Shakespeare also attracted him for tragic inspirations; and of course classic subjects had their turn on his easel.

He continued his work indefatigably, having his pictures very seldom favourably received at the Salon. These were sometimes very large, full of incidents, with many figures. Drawing of Lots in the Boat at Sea, from Byron's *Don Juan*, and the Taking of Constantinople by the Christians, were of that character, and the first-named was one of his noblest creations. In 1845 he was employed to decorate the library of the Luxembourg, that of the Chamber of Deputies in 1847, the ceiling of the Gallery of Apollo in the Louvre in 1849, and that of the Salon de la Paix in the Hotel de Ville in 1853. He died on the 13th August 1863, and in August 1864 an exposition of his works was opened on the Boulevard des Italiens. It contained 174 pictures, many of them of large dimensions, and 303 drawings, showing immense perseverance as well as energy and versatility.

DELAGOA BAY (i.e., in Portuguese, the Bay of the Swampy Land), an inlet on the east coast of South Africa, between 25° 40' and 26° 20' S. lat., with a length from north to south of about 60 miles, and a breadth of about 20. It is protected by a series of islands stretching north from the mainland; and in spite of a bar at the entrance, and a number of shallows within, it forms a valuable harbour, accessible to large vessels at all seasons of the year. The surrounding country is low and very unhealthy, but the island of Luyak has a height of 240 feet, and is used by the natives as a kind of sanatorium. A river 12 or 18 feet deep, variously known as the Manlussa, the Unkomogazi, or King George's River, enters at the north, several smaller streams, the Matolla, the Dandas, and the Tembi, from the Lobombo Mountains, meet towards the middle in the estuary called the English River, and, of greatest importance of all, the Umzati, which has its head-waters in the Draken Berg of the Transvaal settlement, disembogue in the south. The bay was discovered by the Portuguese navigator Vasco da Gama in 1498, and the Portuguese post of Lorenzo Marques was established not long after to the north of the English River. A Dutch settlement was founded in 1720, but in 1730 it was abandoned. In 1822 Captain Owen, finding that the Portuguese seemed to exercise no jurisdiction to the south of Lorenzo Marques, hoisted the English flag and appropriated the country from the Dundas or English River southwards; but, when he visited the bay again in the following year, he found the Portuguese governor, Lupe de Cardenas, in possession, and expelled him. Between the English and Portuguese Governments the question of possession was left undecided till the claims of the republic of Transvaal brought the subject forward. In 1835 the discontented boers, under Orlich, had attempted to form a settlement on the bay; and in 1868 the Transvaalian president, Martin Wessel Petronius, incorporated the country on each side of the Umzati down to the sea. The whole matter in dispute between the three powers was submitted to the arbitration of M. Thiers, the French president, and on April 19, 1875, his successor Marshal Macmahon declared in favour of the Portuguese. In December 1876 the Lisbon Government sent out an expedition of artisans and military workmen to Lorenzo Marques, with a battery of six guns for the defence of the settlement.

See Owen's "Narrative of Voyages," &c., in *Journal of Roy. Geogr. Soc.* 1833, Botelher, *Mem. estat. sobre os dominios Portuguezes na Africa Oriental*, 1835, *Report of the Min. of Marine and*

the Colonies of Portugal, 1863-64; "Baie de Delagoa," in *Bulletin de la Société de Géogr.* 1873.

DELABRE, JEAN BAPTISTE JOSEPH (1749-1822), an eminent mathematician and astronomer, was born at Amiens, September 19, 1749. He commenced his studies in the gymnasium of that town under the celebrated poet Delille, with whom he maintained an intimate friendship till his death. Having obtained an exhibition founded by one of his ancestors for the benefit of the town of Amiens, he was enabled to prosecute his studies for a time at the Collège du Plessis in Paris. The expiry of this privilege, however, left him to struggle with great privations. During the interval in which he was awaiting permanent employment he devoted himself to historical and literary studies. He undertook extensive translations from Latin, Greek, Italian, and English, and at the same time entered on the study of the mathematical sciences. For about a year he supported himself by teaching at Compiègne. On his return to Paris in 1771 he obtained the situation of tutor in the family of D'Assy, the receiver-general of finance. By this time he had resolved to give himself specially to the study of physics and astronomy.

At the College of France he attended the lectures of Lalande, on whose works he had even at that time made a complete commentary. This was first remarked when, in the course of instruction, an occasion presented itself of citing from memory a passage of Aratus. Lalande immediately intrusted to him the most complicated astronomical calculations, and prevailed on D'Assy to establish an observatory at his house, where Delambre applied himself to astronomical observations. In 1781 the discovery of the planet Uranus by Herschel led the Academy of Sciences to propose the determination of its orbit as the subject of one of its annual prizes. Delambre undertook the formation of tables of its motion, and the prize was awarded to him. His next effort was the construction of solar tables, and tables of the motions of Jupiter and Saturn. He took part in the sitting of the Academy of Sciences when Laplace communicated his important discoveries on the inequalities of Jupiter and Saturn; and he formed the design of applying the result of that profound analysis to the completion of tables of the two planets. Delambre turned his attention more especially to the satellites of Jupiter—an undertaking of great difficulty and extent. He had been engaged for several years in the composition of his eclipical tables, when the Academy of Sciences offered a prize for the subject, which was awarded to him. In the same year (1792) he was elected a member of the Academy.

Immediately afterwards he was appointed, along with Méchain, by the French section of the joint English and French commission to measure an arc from Dunkirk to Barcelona as a basis for the metric system. This undertaking, in itself laborious, was rendered highly dangerous to the personal safety of those engaged in it by the events of the Revolution. Méchain died whilst the work was proceeding; and its successful termination in 1799 was due to the ability and the prudence of Delambre. A full and interesting account of the work was published in his *Base du Système Métrique Décimal* (3 vols 1806-10), for which he obtained, by a unanimous vote, the prize awarded by the National Institute of France to the most important work in physical science of the preceding ten years.

Delambre, who had been chosen as an associate of almost every scientific body in Europe, was appointed in 1795 a member of the French Board of Longitude, and in 1803 perpetual secretary for the mathematical sciences in the Institute. In 1807 he succeeded Lalande in the chair of astronomy of the College of France, and he was appointed one of the principal directors (*titulaires*) of the university.

For twenty years he performed faithfully and impartially the duties of his office in one of the classes of the Institute. His annual reports, his historical *éloges*, which have been published, and his exposition of the progress of science are eminently distinguished by profound erudition, literary skill, and, above all, by generous appreciation of the works of others. His literary and scientific labours were very numerous, and, in respect of excellence, of the highest order. His *History of Astronomy*, published at intervals, and forming when complete six quarto volumes, is a work of prodigious research. It puts the modern astronomer in possession of all that had been done, and of the methods employed by those who lived before him.

His *Méthodes Analytiques pour la Détermination d'un Arc du Méridien*, his numerous memoirs in the additions to the *Connaissances des Temps*, and his *Astronomie Théorique et Pratique* exhibit the finest applications of modern analysis to astronomy and geography.

It is a remarkable fact that Delambre did not apply himself to astronomical observations until he had reached the comparatively late age of thirty-five. He was appointed a member of the Royal Council of Public Instruction in 1814; but he lost the place in 1815. He was in Paris when it was taken by the allied armies; and, in a letter written at that time to a friend and pupil, he says that on the day of the siege, in the hearing of the cannonade, he laboured with tranquillity in his study from eight in the morning till midnight. He had a happier fate than Archimedes in a like position, for he was not molested by the victors, and no one was billeted on him, probably from respect to his high reputation. At the creation of the Legion of Honour in 1802 Delambre was made a member of that order. He was appointed chevalier of St Michael in 1817, an officer in the Legion of Honour in 1821; but a long time before, he had been created an hereditary chevalier, with an endowment, which was decreed as a national reward.

The life of continued and hard study which Delambre led at last affected his health. The disease by which he was cut off became apparent in the month of July 1822. His total loss of strength, with frequent and long continued fainting-fits, gave warning of a fatal result, which occurred on the 19th August 1822.

The following is a list of his works which appeared separately:—*Tables de Jupiter et de Saturne* (1789); *Tables du Soleil, de Jupiter, de Saturne, d'Uranus, et des Satellites de Jupiter, pour servir à la 3me édition l'Astronomie de Lalande* (1792); *Méthodes Analytiques pour la Détermination d'un Arc du Méridien* (1799); *Tables Trigonométriques Décimales, par Borda, revues, augmentées, et publiées par M. Delambre*, (1801); *Tables du Soleil, publiées par le Bureau des Longitudes* (1806); *Base du Système Métrique Décimal*, &c. (3 vols in 4to, 1806–1810); *Rapport Historique sur les Progrès des Sciences Mathématiques depuis 1789*, &c. (1810); *Abregé d'Astronomie, ou Leçons Élémentaires d'Astronomie Théorique et Pratique*, in 8vo; *Astronomie Théorique et Pratique* (3 vols in 4to, 1814); *Tables Écliptiques des Satellites de Jupiter* (1817); *Histoire de l'Astronomie Ancienne* (2 vols in 4to, 1817); *Histoire de l'Astronomie du Moyen Age* (1819, 1 vol. in 4to); *Histoire de l'Astronomie Moderne* (1821, 2 vols in 4to); *Histoire de l'Astronomie au Dix-huitième Siècle* (1 vol. 4to, 1827). In addition to these, he furnished a very considerable number of memoirs (about 28) on various points of astronomy to the *Connaissances des Temps*, beginning with the year 1788. He also contributed to the Memoirs of the Academies of Stockholm, St Petersburg, Berlin, and Turin, and to those of the first class of the French Institute; and he composed *éloges* on many of his contemporaries at their death.

DE LA RIVE, AUGUSTE (1801–1873), a Swiss physicist, distinguished chiefly for his researches on the subject of electricity, was born at Geneva on the 9th October 1801. He belonged to a good family closely connected with that of the Count Cavour, and he inherited his taste for natural science from his father, an eminent physician and chemist. After an unusually brilliant career as a student, he was ap-

pointed at the early age of twenty-two to the chair of natural philosophy in the Academy of Geneva. For some years after his appointment he devoted himself specially to the investigation of the specific heat of gases, and to observations for determining the temperature of the earth's crust. In the latter inquiry he availed himself of an artesian well that had been bored to a depth of 700 feet, and his observations were adopted by Poisson as the basis of his calculations. The comparatively new subject of electricity, however, received much of his attention from the first, and it gradually became the chief object of his scientific work. His name is associated with original discoveries in connection with magnetism, electro-dynamics, the connection of magnetism with electricity, the properties of the voltaic arc, and the passage of electricity through extremely rarefied media. His researches on the last-mentioned subject led him to form a new theory of the aurora borealis, which, though not free from difficulties, is on the whole the most probable explanation of a very obscure phenomenon. The most valuable practical result of his scientific discoveries was the process of electro-gilding carried out by Messrs Elkington & Ruolz from a memoir which he communicated to the Académie des Sciences. By making it known in this way he voluntarily renounced all the profits of his discovery. Between 1853 and 1858 De la Rive published a complete treatise on electricity in three octavo volumes, which was regarded as a work of high authority, and was at once translated into English, German, and Italian. Its author's scientific reputation received the usual recognition in his election to the membership of most of the learned societies of Europe. In 1842 he received the grand prize of 3000 francs from the Académie des Sciences for his discovery of the electro-gilding process; and in 1864 he received the highest honour open to the scientific men of Europe in his nomination as one of the eight foreign associates of the Academy. De la Rive's birth and fortune gave him considerable social and political influence. He was distinguished for his hospitality to literary and scientific men, and for his interest in the welfare and independence of his native country. In 1860, when the annexation of Savoy and Nice had led the Genevese to fear French aggression, De la Rive was sent by his fellow-citizens on a special embassy to England, and succeeded in securing a declaration from the English Government, which was communicated privately to that of France, that any attack upon Geneva would be regarded as a *casus belli*. On the occasion of this visit the university of Oxford conferred upon De la Rive the honorary degree of D.C.L. When on his way to pass the winter at Cannes he died suddenly at Marseilles, on the 28th November 1873.

DELAROCHE, HIPPOLYTE, commonly known as PAUL (1797–1856), one of the most accomplished painters of the eclectic modern school, was born in Paris, 17th July 1797. He is always spoken of as one of the most fortunate and successful of men, as well as one of the ablest, since he never appeared to encounter any obstacles or to feel any difficulties.

The father of Delaroche was an expert who had made a fortune, to some extent, by negotiating and cataloguing, buying and selling. He was proud of his son's talent, and able to forward his artistic education. The master selected was Gros, then painting life-size histories, and surrounded by many pupils. In this *atelier* Delaroche met Bouington (an English youth of whose work we see little, but who has had a very considerable influence in France), Roqueplan, Bellangé, Eugène Lami, and others. In no haste to make an appearance in the Salon, his first exhibited picture was a large one, Josabeth saving Joas, 1822. This picture led to his acquaintance with Géricault and Delacroix, with whom he remained on the most friendly terms, the three

forming the central group of a numerous body of historical painters, such as perhaps never before lived in one locality and at one time.

From 1822 the record of his life is to be found in the successive works coming from his hand. He visited Italy in 1838 and 1843, when his father-in-law, Horace Vernet, was director of the French Academy. His studio in Paris was in the Rue Mazarine, where he never spent a day without some good result, his hand being sure and his knowledge great. His subjects, definitely expressed and popular in their manner of treatment, illustrating certain views of history dear to partisans, yet romantic in their general interest, were painted with a firm, solid, smooth surface, which gave an appearance of the highest finish. This solidity, found also on the canvas of Vernet, Scheffer, Leopold Robert, and Ingres, was the manner of the day. It repudiates the technical charm of texture and variety of handling which the English school inherits as a tradition from the time of Reynolds; but it is more easily understood by the world at large, since a picture so executed depends for its interest rather on the history, scene in nature, or object depicted, than on the executive skill, which may or may not be critically appreciated. We may add, that his point of view of the historical characters which he treated is not always just, whatever self-command we may give him credit for. Cromwell lifting the Coffin and looking at the Body of Charles is an incident only to be excused by an improbable tradition; but the King in the Guard-Room, with villainous round-head soldiers blowing tobacco smoke in his patient face, is a libel on the Puritans, and Queen Elizabeth dying on the Ground, like a she-dragon no one dares to touch, is sensational; while the Execution of Lady Jane Grey is represented as taking place in a dungeon. Nothing can be more incorrect than this last as a reading of English history, yet we forget the inaccuracy in admiration of the treatment which represents Lady Jane, with bandaged sight, feeling for the block, her maids covering their faces, and none with their eyes visible among the many figures. On the other hand, Strafford led to Execution, when Laud stretches his lawn-covered arms out of the small high window of his cell to give him a blessing as he passes along the corridor, is perfect, and the splendid scene of Richelieu in his gorgeous barge, preceding the boat containing Cinq-Mars and De Thou carried to execution by their guards, is perhaps the most dramatic semi-historical work ever done. The Princes in the Tower must also be mentioned as a very complete creation, and the young female Martyr floating dead on the Tiber is so pathetic that criticism feels hard-hearted and ashamed before it. As a realization of a page of authentic history, again, no picture can surpass the Assassination of the Duc de Guise at Blois. The expression of the murdered man stretched out by the side of the bed, the conspirators all massed together towards the door and far from the body, show exact study as well as insight into human nature. This work was exhibited in his meridian time, 1835; and in the same year he exhibited the Head of an Angel, a study from Horace Vernet's young daughter Louise, the love of whom was the absorbing passion of his life, and from the shock of whose death, in 1845, it is said he never quite recovered. By far the finest productions of his pencil after her death are of the most serious character, a sequence of small elaborate pictures of incidents in the Passion. Two of these, the Virgin and the other Maries, with the apostles Peter and John, within a nearly dark apartment, bearing the crowd as it passes halting Christ to Calvary, and St John conducting the Virgin home again after all is over, are beyond all praise as exhibiting the divine story from a simply human point of view. They are pure and elevated, and also dramatic and painful. Delaroche was not

troubled by ideals, and had no affectation of them. His sound but hard execution allowed no mystery to intervene between him and his *motif*, which was always intelligible to the million, so that he escaped all the waste of energy that painters who try to be poets on canvas suffer. Thus it is that essentially the same treatment was applied by him to the characters of distant historical times, the founders of the Christian religion, and the real people of his own day, such as Napoleon at Fontainebleau, or at St Helena, or Maria Antoinette leaving the Convention after her sentence.

In 1837 Delaroche received the commission for the great picture, 27 metres long, in the hemicycle of the lecture theatre of the École des Beaux Arts. This represents the great artists of the modern ages assembled in groups on either hand of a central elevation of white marble steps, on the topmost of which are three thrones filled by the architects and sculptors of the Parthenon. To supply the female element in this vast composition he introduced the geniuses or muses, who symbolize or reign over the arts, leaning against the balustrade of the steps, beautiful and queenly figures with a certain antique perfection of form, but not informed by any wonderful or profound expression. The portrait figures are nearly all unexceptionable and admirable. This great and successful work is on the wall itself, an inner wall however, and is executed in oil. It was finished in 1841, and considerably injured by a fire which occurred in 1855, which injury he immediately set him to remedy; but he died before he had well begun, on the 11th November 1856. Robert Fleury finished the repair, and the picture as yet shows no sign of decay.

Personally Delaroche exercised even a greater influence than by his works. Though short and not powerfully made, he impressed every one as rather tall than otherwise; his physiognomy was accentuated and firm, and his fine forehead gave him the air of a minister of state. (W. R. S.)

DELAHUE, GUYARD (1751-1835), a French historical investigator, and one of the chief authorities on Norman and Anglo-Norman literature. He was a native of Caen, received his education at the university of that town, and was ultimately raised to the rank of professor. His first historical enterprise was interrupted by the French Revolution, which forced him to take refuge in England; but the interruption was the less to be regretted as he found the fullest encouragement from his northern compatriots, and had the opportunity of examining a vast mass of original documents in the Tower and elsewhere, which proved of the utmost assistance to his investigations. In the preface to the second volume of his greatest work—the *Essais historiques*—he speaks feelingly of the kindness he had experienced, and mentions his supreme gratification at receiving the approval of Sir Walter Scott. From England he passed over to Holland still in prosecution of his favourite task, and there he remained till 1798, when the way was open for his return to France. The rest of his life was spent in his native town, where he was chosen principal of his university. While in England he had been elected a member of the Royal Society of Antiquaries, and in his own country he was made a corresponding member of the Institute, and was enrolled in the Legion of Honour.

Besides numerous articles in the *Memoirs of the Royal Society of London*, the *Memoires de l'Institut*, the *Memoires de la Société d'Agriculture de Caen*, and in other periodical collections, he published separately *Essais historiques sur les Bardes, les Jongleurs, et les Trouvères normands et anglo-normands*, 3 vols. 1834, and *Recherches historiques sur la Prairie de Caen*, 1837, and since his death have appeared *Memoires historiques sur le palais de Caen*, 1841; *Recherches sur la tapisserie de Bayeux*, 1841; and *Nouveaux Essais historiques sur la ville de Caen*, 1842. In all his writings he displays a strong partiality for everything Norman, and rates the Norman influence on French and English literature as of the very highest moment.

DELAVIGNE, JEAN FRANÇOIS CASIMIR (1793-1843), French poet and dramatist, was born April 4, 1793, at Havre, whence his father sent him at an early age to Paris, there to be educated at the Lycée Napoléon. During the first years of his attendance at this school he was little else than a dullard, but on reaching the age of fourteen he seems to have undergone a complete change—sluggishness gave place to unusual facility in the acquisition of knowledge; a decided taste for literary studies, especially poetry, was evinced; and he quickly became a distinguished student. He read with avidity all the poets, great and small, to whose works access was obtainable, and was known to spend many an hour snatched from school duties in the elaboration of his own juvenile pieces. Constitutionally of an ardent and sympathetic temperament, with a mind the natural intelligence of which was quickened by extensive miscellaneous reading, and by contact with a world then in a state of revolutionary ferment, it will be seen that Delavigne had much in his favour when he first sought popular applause. An opportunity for display soon presented itself. On the 20th of March 1811 the Empress Marie Louise gave birth to a son, christened in his very cradle king of Rome. This long desired event was hailed with the utmost satisfaction; congratulations reached Napoleon from every quarter of Europe, and fifty millions of human beings did homage to their future sovereign. But the poets were dumb. Our young aspirant to fame, therefore, seeing the field unoccupied, composed a festal hymn. It was completely successful; even the critics were pleased. On being shown the verses, Andrieux, albeit a man little disposed to flatter, exclaimed, "Bring him to me! He shall make nothing but verses, and these, I hope, good ones." Encouragement such as this augured well for the future; but Delavigne's purse was scantily furnished, and his friends were poor and unable to render any assistance. At this point he was fortunate in securing as a patron Count François of Nantes, who attached him to the revenue office, but with the single proviso, that he should not trouble himself to appear at his post oftener than once a month.

About this time he competed twice for an academy prize, but without success. A victory, however, was at hand. Amid the throes in which society laboured at the period of Napoleon's downfall, Delavigne, catching inspiration from the mingled hopes and fears which agitated his fellow-countrymen, burst upon the world with two impassioned poems, the first entitled *Waterloo*, the second, *Dévastation du Musée*, both written in the heat of patriotic enthusiasm, and teeming with popular political allusions. A third, but of inferior merit, *Sur le besoin de s'unir après le départ des étrangers*, was afterwards added. These stirring pieces, termed by him *Messéniques*, sounded a key-note which found an echo in the hearts of all. Twenty-five thousand copies were sold; Delavigne was famous. Nor was his reputation made solely with the populace, his verses were the subject of much discussion in court circles; and in spite of their political tone it was thought necessary to bestow upon him some mark of attention. He was therefore appointed to an honorary librarianship, with no duties to discharge. Thus was he fortunately rendered independent by the offer of one sinecure just as he was deprived of another, for his intercourse with François had now ceased.

Having achieved so signal a triumph in one department of literature, Delavigne was desirous of attaining distinction in another, and accordingly brought out upon the stage a play well-known under the title of *Les Vêpres Siciliennes*. The manuscript having been refused at the Théâtre-Français, the critic of which, a supercilious poetaster, told him that "some day he might write comedy very fairly," the mortified author, like Voltaire on a similar occasion,

cast the sheets into the flames, from which they were rescued by his brother Germain. A better fate than burning awaited the piece, and in 1819 it was performed at the Odéon, then just rebuilt. On the night of the first representation, which was warmly received, Picard, the manager, threw himself into the arms of his elated friend, exclaiming, "You have saved us! You are the founder of the second French Theatre." This was followed up by the production of the *Comédiens* (1820), a poor play, with little plot, and the *Paria* (1821), with still less, but containing some well-written choruses. The latter piece obtained a longer lease of life than its intrinsic literary merits warranted, on account of the popularity of the political opinions freely expressed in it—so freely expressed, indeed, that the displeasure of the king was incurred, and Delavigne lost his post. But the duke of Orleans, willing to gain the people's good wishes by complimenting their favourite, wrote to him as follows,— "The thunder has descended on your house; I offer you an apartment in mine." Accordingly he became librarian at the Palais-Royal, a position retained during the remainder of his life. It was here that he wrote the *École des Vicillards*, which gained his election to the Academy in 1825. To this period also belong *La Princesse Amélie* (1828), and *Marino Faliero* (1829), a drama in the romantic style.

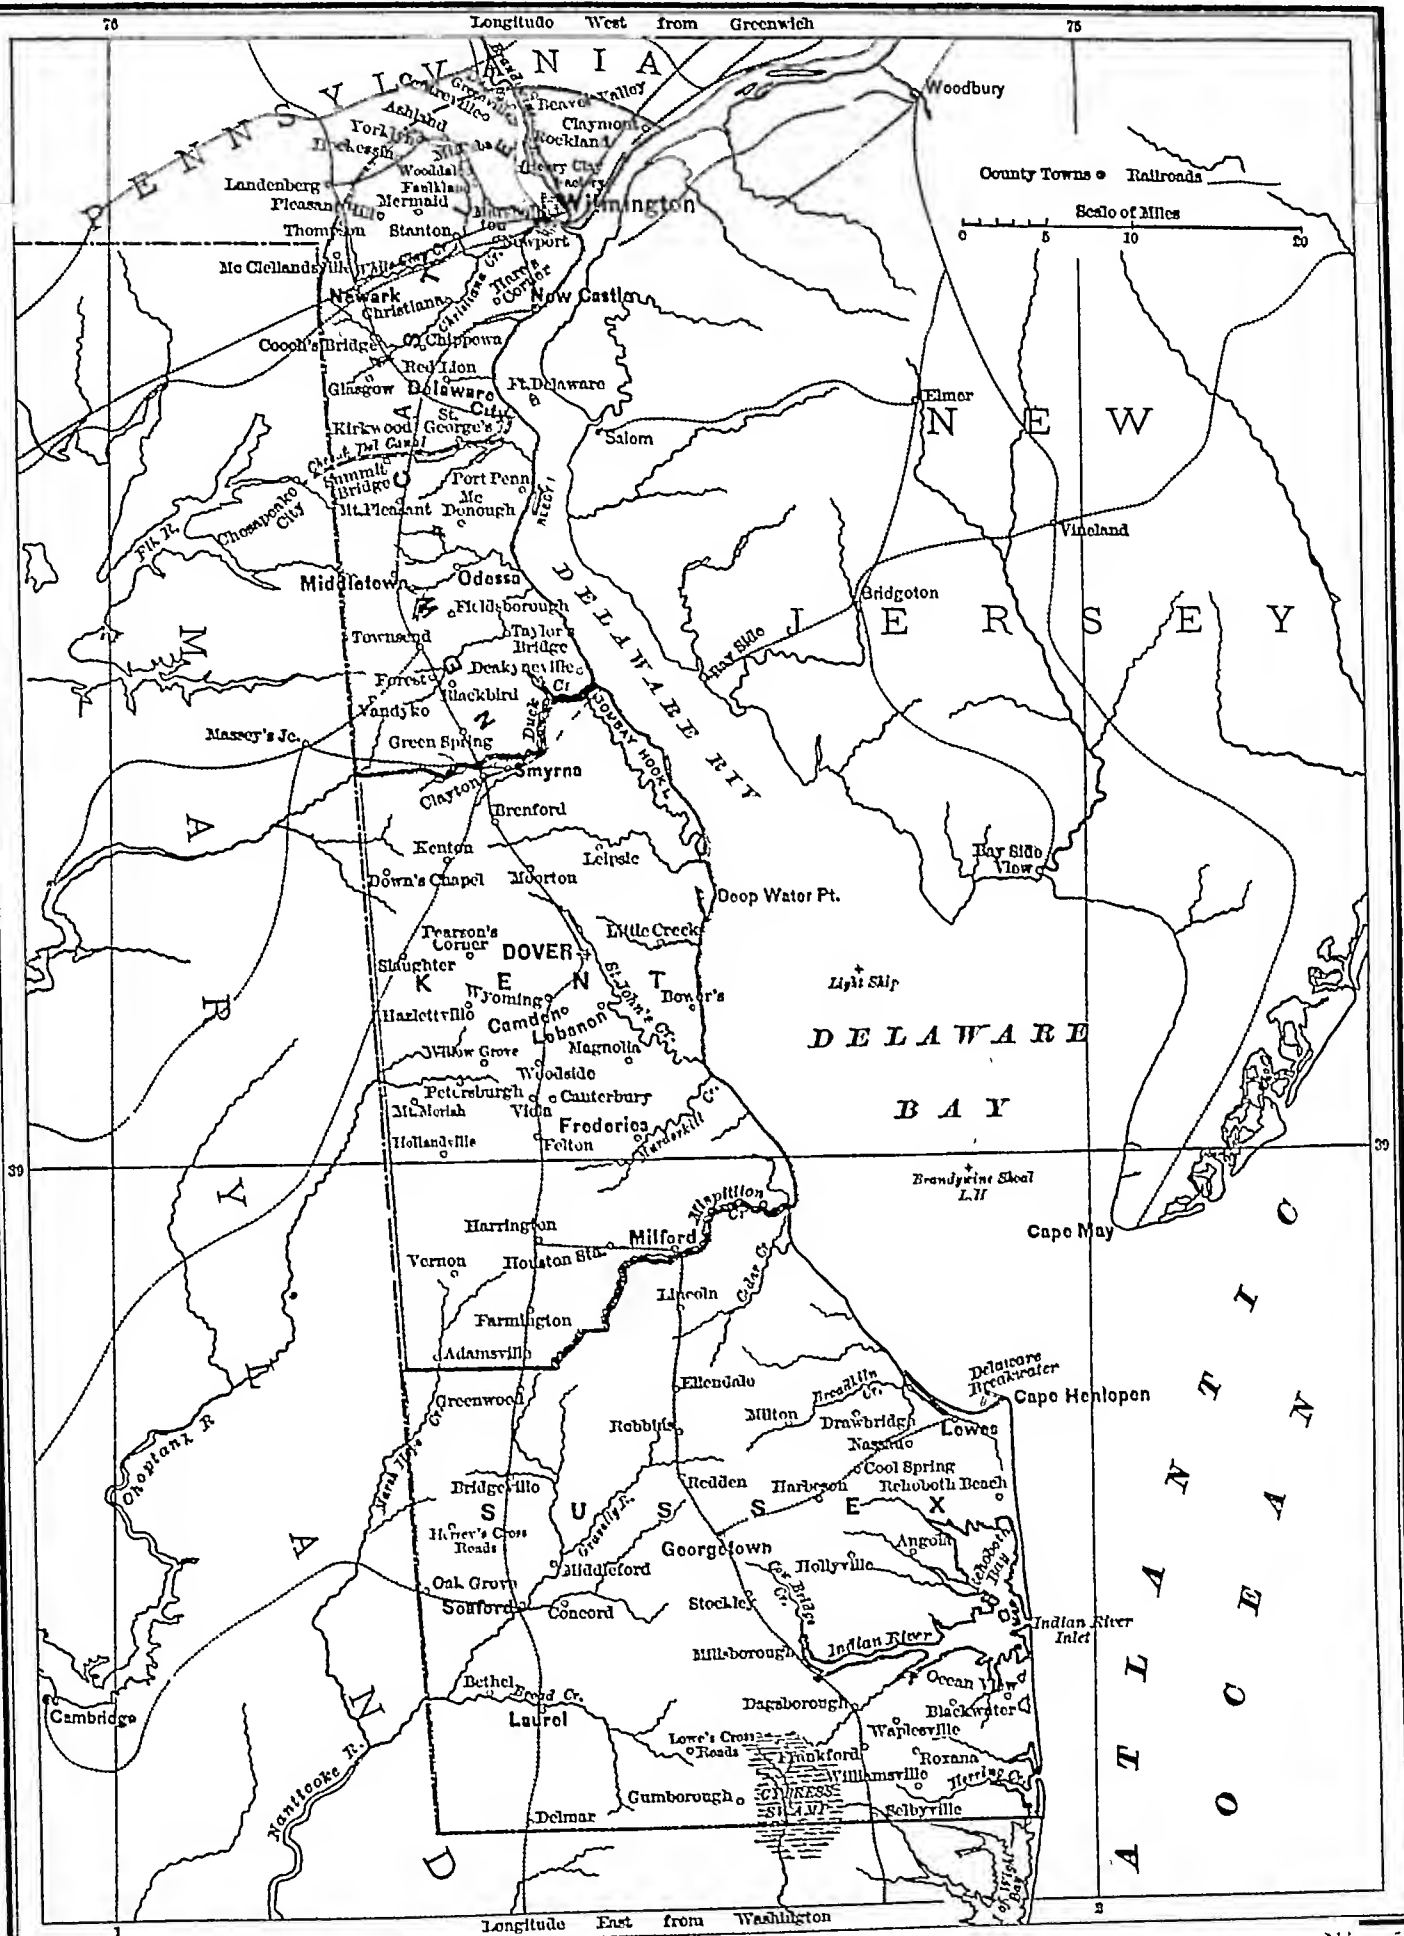

For his success as a writer Delavigne was in no small measure indebted to the stirring nature of the times in which he lived. The *Messéniques*, which first introduced him to universal notice, had their origin in the excitement consequent on the occupation of France by the allies in 1815. Another crisis in his life and in the history of his country, the revolution of 1830, stimulated him to the production of a second masterpiece, *La Paroissienne*. This song, set to music by Auler, was on the lips of every Frenchman, and rivalled in popularity the celebrated *Marseillaise*. A companion piece, *La Varsouvienne*, was written for the Poles, by whom it was sung on the march to battle.

Other works of Delavigne followed each other in rapid succession,—*Don Juan d'Autriche* (1835), *Une Famille au temps du Luther* (1836), *La Popularité* (1838), *La Fille du Cid* (1839), *Le Conseiller rapporteur* (1841), and *Charles VI.* (1843), an opera partly written by his brother.

But the poet had reached the acme of his reputation, and was now on the decline. In 1843 he quitted Paris to seek in Italy the health his labours had cost him. At Lyons his strength altogether gave way, and on the 11th of December, while listening to his wife, who read aloud one of Scott's novels, he gently expired, murmuring some verses.

By many of his own time Delavigne was looked upon as unsurpassed and unsurpassable. Every one bought his works; nay more, every one read them. If a new play of his was announced at the theatre, it was the affair of a month to secure a seat. Talma and Mademoiselle Mars felt honoured in receiving from him a part; theatrical managers lay in wait for the fruits of his pen. But the applause of the moment was gained at the sacrifice of lasting fame. Delavigne wrote but for the hour; he was too little the retired, contemplative poet, and too much the busy man of the world. In the region of politics alone does he shine; when he quits this sphere it is to descend to the level of utter commonplace.

But as a writer Delavigne had many excellencies. He is never at a loss for language, yet expresses himself in a terse and vigorous style. The poet of reason rather than of imagination, he recognizes his own province, and is rarely tempted to flights of fancy beyond his powers. He wrote always as he would have spoken, from sincere conviction.

Court of Chaucery in England, and pending the trial the "three lower counties" were not sure to whom they belonged, and so paid no land rents. In 1768 the suit was decided, and commissioners appointed, who defined the boundary line of Maryland as it now stands. It was in the year 1776 that the first constitution of the State of Delaware was framed, whereby "the three lower counties on the Delaware" lost their awkward name, and again had a new form of government. In the same year Delaware, as one of the thirteen colonies, signed the Declaration of Independence; and in 1787 the State, in convention, adopted the constitution of the United States. In 1792 a new State constitution was enacted, and again in 1831, which is now in force. Under it, the governor is elected for four years, and the legislature meets biennially at Dover, the State capital. Delaware was one of the original thirteen States, and, though slave-holding, remained loyal to the Union at the secession of the Southern States in 1861.

DELAWARE, a city of the United States, capital of a county of the same name in Ohio, is situated on the west bank of the Olentangy, nearly in the centre of the State, 24 miles north of Columbus. Its principal public institutions are the Ohio Wesleyan university and a female college belonging to the same body. The manufactures consist of oil, cordage, hempen cloth, and iron work. A medicinal spring in the neighborhood is resorted to for the benefit of its waters. Population (1870), 5641.

DEL CREDERE AGENT is one who, selling goods for his principal on credit, undertakes for an additional commission to guarantee the solvency of the purchaser.

DELFICO, MELCHIORRE (1744-1835), an eminent Italian writer on political economy, was born at Teramo in the Abruzzi on the 1st August 1744, and was educated at Naples. He devoted himself specially to the study of jurisprudence and political economy, and thus qualified himself for the valuable service he was to render to his native country by his writings on legal and economic subjects. His first publication, *Saggio filosofico nel matrimonio* (1774), was an eloquent vindication of marriage against the loose views that were prevalent. To his *Memorie sul Tribunale della Grascia e sulle Legge Economiche nelle Provincie confinante del Regno*, addressed to the king, the Neapolitans owed the abolition of the most vexatious and absurd restrictions on the sale and exportation of agricultural produce. Other *Memorie* on kindred subjects followed, and did much to promote reform in the direction of free trade. Equally beneficial was the adoption of the principles developed in his *Riflessioni sulla Vendita dei Feudi Devoluti*, in 1790, and his *Lettera al Duca di Cantalupo su i Feudi Devoluti*, in 1795, which were so powerfully reasoned that a law was promulgated for the sale of all feudalities reverting to the crown as free estates. During the short reign of Joseph Bonaparte at Naples, Delfico was made a councillor of state, and employed in the formation of the new judicial organization of Naples. He was employed in a similar manner under Murat; and, when Ferdinand was restored in 1815, Delfico was made president of the commission of the archives, an office which he filled until 1823, when he tendered his resignation on account of his advanced age. His sovereign acknowledged his eminently patriotic services by the grant of a large pension for life. Soon after, he retired to his native town, where he died on the 21st June 1835, at the advanced age of ninety-one. Besides the works we have noticed, on which his Neapolitan fame may be said chiefly to rest, we owe to him several general works of no mean reputation, especially *Ricerche sul vero Carattere della Giurisprudenza Romana, e di sue Culture*, 1790, and *Pensieri sulla Storia, e sull' Incertezza ed Inutilità*

della Medesima, 1806, which have both been several times reprinted. In the latter he has anticipated the scepticism of Niebuhr on the early history of Rome, which he treats as fabulous; and he denies to the Romans before the second Punic war all arts but that of agriculture, and of making war on their neighbours.

See Gregoire de Filippis Delfico's *Della Vita e delle Opere di Melchiorre Delfico* (Teramo, 1836), and Tiplado's *Biografia degli Italiani illustri* (vol. ii).

DELFT, a town of Holland, in the province of South Holland, on the Schie, nearly ten miles from Rotterdam, and in the line of the canal between that city and the Hague. It is well and regularly built in the form of a square, but has a rather gloomy appearance from its streets being traversed by narrow stagnant canals. The public buildings comprise the Prinsenhof, or palace, where William of Orange was assassinated in 1584, the town-house, erected in 1618, with antiquarian and artistic collections; the Old Church, dating from the 11th century, and containing monuments to Van Tromp and Piet Hein, and the tomb of Leeuwenhoek, the naturalist; the New Church, founded in 1381, and interesting both for its chime of 500 bells, and as the burial-place of the princes of the house of Orange from the days of the Liberator down to the present century; the arsenal, originally erected as a warehouse for the East India Company; and the polytechnic school, with the fine collection of mechanical models formerly preserved in the dockyard at Amsterdam. It is sufficient to mention the powder-magazine, the school of military engineering, the theatre, the municipal school for the education of civil service students for the colonies, the school of design, the lunatic asylum, and Madame Renswonde's orphanage. For a long time the name of Delft was associated, not only in Holland, but even abroad, with the manufacture of excellent earthenware, but this industry, as well as the beer-brewing which was of great importance last century, has become almost extinct. The present branches are carpet-weaving, cooperage, dyeing, and distilling. The town was founded about 1075 by Duke Geoffrey of Lorraine after his conquest of Holland from Count Thierry. It was almost totally ravaged by fire in 1536; and in 1654 it lost about 1200 of its population by the explosion of a powder-magazine. In 1797 the *Christo Sacrum* Society was founded by Onder van Vyngaard-Cenzius, the burgomaster of the city, for the utopian purpose of uniting in one community all the various branches of the Christian church. Of the celebrities of the town the most famous is Grotius, whose tomb is shown in the New Church. Population in 1874, 23,900.

DELHI,¹ a district of British India under the jurisdiction of the lieutenant-governor of the Punjab, situated between 28° 13' and 29° 13' N. lat. and 76° 53' and 77° 34' E. long. It consists of a strip of territory on the right or west bank of the River Jumna, 75 miles in length, and varying from 15 to 23 miles in breadth, bounded on the N. by the district of Karnal, on the E. by the Jumna river separating it from Meerut (Mirat) and Bulandshahr districts, on the S. by Rohtak, and on the W. by Gurgaon. With the exception of a low-lying alluvial tract in the north, and a narrow fringe of fertile soil along the river bank to the south of Delhi city, the country consists of stony or hard sandy soil, where cultivation mainly depends upon artificial irrigation. This is supplied by the Western Jumna canal, which has a course of 51 miles in the district; by the Ali Murdan canal, constructed by a celebrated Persian nobleman of that name; by the new Agra canal;

¹ The name is also applied to a Division or Commissionership, comprising the districts of Delhi, Gurgaon, and Karnal, containing a total area of 5557 square miles, with a population of 1,920,912.

ance, and forms a marked contrast to the south-west quarter of the town, which is densely occupied by the shops and dwellings of the native population.

The buildings in the native town are chiefly of brick, well-built and substantial. The smaller streets are narrow and tortuous, and in many cases end in *culs de sac*. On the other hand, no city in India has finer streets than the main thoroughfares of Delhi, ten in number, thoroughly drained, metalled, and lighted. The principal thoroughfare, the Chāndni Chāuk, or Street of Silver, leads eastwards from the fort to the Lahore gate, and is three-quarters of a mile long by 74 feet broad. Throughout the greater part of its length, a double row of *nīm* and *pīpāl* trees runs down its centre on both sides of a raised path, which has taken the place of the masonry aqueduct that in former days conducted water from the canal into the palace. A little to the south of the Chāndni Chāuk is the Jāmā Masjid, or great mosque, standing out boldly from a small rocky rising ground. Begun by Shāh Jahān in the fourth year of his reign, and completed in the tenth, it still remains one of the finest buildings of its kind in India. Its front court-yard, 450 feet square, and surrounded by a cloister open on both sides, is paved with granite inlaid with marble, and commands a view of the whole city. The mosque itself, a splendid structure forming an oblong 261 feet in length, is approached by a magnificent flight of stone steps. Three domes of white marble rise from its roof, with two tall and graceful minarets at the corners in front. The interior of the mosque is paved throughout with white marble, and the walls and roof are lined with the same material. Two other mosques in Delhi deserve a passing notice,—the Kālā Masjid, or black mosque, so called from the dark colour given to it by time, and supposed to have been built by one of the early Afghan sovereigns, and the mosque of Roshān-ud-daulā. Among the more modern buildings of Delhi may be mentioned the Government College, founded in 1792, the Residency, and the Protestant church, built at a cost £10,000, by Colonel Skinner, an officer well-known in the history of the East India Company. About half-way down the Chāndni Chāuk is a high clock-tower, with the institute and museum opposite. Behind the Chāndni Chāuk, to the north, lie the Queen's Gardens; beyond them the "city lines" stretch away as far as the well-known rocky ridge, about a mile outside the town. From the summit of this ridge the view of the station and city is very picturesque. To the west and north-west, considerable suburbs cluster beyond the walls, containing the tombs of the imperial family. That of Humāyūn, the second of the Mughul dynasty, is a noble building of granite inlaid with marble. It lies about two miles from the city, amid a large garden of terraces and fountains, the whole surrounded by an embattled wall, with towers and four gateways. In the centre stands a platform about 20 feet high by 200 feet square, supported by cloisters, and ascended by four great flights of granite steps. Above, rises the Mausoleum, also a square, with a great dome of white marble in the centre. About a mile to the westward is another burying-ground, or collection of tombs and small mosques, some of them very beautiful. The most remarkable is perhaps the little chapel in honour of a celebrated Mussulman saint, Nizām-ud-dīn, near whose shrine the members of the late imperial family, up to the time of the mutiny, lie buried, each in his own little inclosure, surrounded by very elegant lattice-work of white marble. The Kutab Minār, or Pillar, is situated about nine miles south of the city.

The palaces of the nobles, which formerly gave an air of grandeur to the city, have for the most part disappeared. Their sites are occupied by structures of less pretension, but

still of some elegance of architectural design. The city is now amply supplied with water, and much attention has of late been paid to its cleanliness and its sanitary condition generally. The principal local institution was, until 1877, the Delhi College, founded in 1792. It was at first exclusively an Oriental school, supported by the voluntary contributions of Mahometan gentlemen, and managed by a committee of the subscribers. In 1829 an English department was added to it; and in 1855 the institution was placed under the control of the Educational Department. In the mutiny of 1857 the old college was plundered of a very valuable Oriental library, and the building completely destroyed. A new college was founded in 1858, and was affiliated to the university of Calcutta in 1864. The old college attained to great celebrity as an educational institution, and produced many excellent scholars. Under orders of the Government of the Punjab (February 1877), the collegiate staff of teachers was to be withdrawn, in order to concentrate the grant available for higher-class education upon the central and more useful institution at Lahore, the present capital of the province.

The population of Delhi in 1853 was returned at 152,424, viz., 76,390 Hindus and 76,034 Mahometans. In 1868, the census showed that since the Mutiny the Mahometan population had greatly diminished, while on the other hand the Hindus had considerably increased. In that year, the population was ascertained to be made up as follows—Hindus, 85,087 (males 46,541 and females 38,546); Mahometans, 61,720 (males 32,361 and females 29,359); Sikhs, 357 (males 267 and females 90), other denominations, 7253 (males 4177 and females 3076) total of all religions, 154,417 (males 83,346 and females 71,071). The Delhi municipality, which also embraces the suburbs, contains a population of 184,840. The total income (mainly derived from octroi duties) in 1871-72 amounted to £25,610, or an average of 2s 9½d per head.

History.—From the earliest period of Indian history, Delhi or its immediate neighbourhood has been the site of a capital city. Within the circuit of a very few miles from modern Delhi, city after city has risen upon the ruins of its predecessors, and the debris of ancient buildings is now estimated to cover an area of 45 square miles. The first of these fallen capitals, Indraprastha, is supposed to date from the 15th century B.C., when the Aryan colonists of India were beginning to feel their way down the Jumna. The Sanskrit epic, the *Mahābhārata*, relates how the city was founded by Yudhisthira and his brothers, the five Pāndavas. It lay upon the banks of the Jumna, near Humāyūn's tomb, about two miles south of the modern city; and the Migambod *ghāt*, near the old Calcutta gate of Delhi, is believed to be its one surviving relic. A list of monarchs brings the history of Indraprastha down to the middle of the 1st century B.C., when the name of Dilli, or Delhi, is first met with. By this time the city had spread or been removed some miles to the south, as far as the site now occupied by the Kutab Minār. Another blank of several centuries occurs until the 3d or 4th century A.D. To this latter period belongs the carved iron pillar near Delhi, one of the most curious monuments in India. It consists of a solid shaft of wrought iron, upwards of 16 inches in diameter, and more than 50 feet in length, of which 22 feet are above ground. The pillar bears a Sanskrit inscription in six lines, recording the history of one Rājā Dhāva, who "obtained by his own arm an undivided sovereignty on the earth for a long period." Delhi next makes its appearance in history at the time of the foundation of the Tomāra or Thār dynasty by Auang Pal in 736 A.D. This ruler is said to have restored the city, and during his dynasty the capital alternated between Delhi and Kannuj. About 1151 A.D. the Tomāra dynasty was overthrown by Visala Deva, the Chohan king of Ajmir, but a marriage of the daughter of the vanquished monarch to the son of the conqueror united the two families. The son of this union, the famous

Lientenant Willoughby subsequently died of his injuries; the remaining three succeeded in making their escape. The occupation of Delhi by the rebels was the signal for risings in almost every military station in North-Western India. The revolted soldiery with one accord thronged towards Delhi, and in a short time the city was garrisoned by a rebel army variously estimated at from 50,000 to 70,000 disciplined men. The pensioned king, Bahádur Sháh, was proclaimed emperor; his sons were appointed to various military commands. About fifty Europeans and Eurasians, nearly all females, who had been captured in trying to escape from the town on the day of the outbreak, were confined in a stifling chamber of the palace for fifteen days; they were then brought out and massacred in the court-yard.

The siege which followed forms one of the memorable incidents of the British history of India. On the 8th June, four weeks after the outbreak, Sir H. Barnard, who had succeeded as commander-in-chief on the death of General Anson, routed the mutineers with a handful of Europeans and Sikhs, after a severe action at Badli-ka-Sarai, and encamped upon the ridge that overlooks the city. The force was too weak to capture the city, and he had no siege train or heavy guns. All that could be done was to hold the position till the arrival of reinforcements and of a siege train. During the next three months the little British force on the ridge were rather the besieged than the besiegers. Almost daily sallies, which often turned into pitched battles, were made by the rebels upon the over-worked handful of Europeans, Sikhs, and Gurkhas. A great struggle took place on the centenary of the battle of Plassey, June 23, and another on the 25th August; but on both occasions the mutineers were repulsed with heavy loss. General Barnard died of cholera in July, and was succeeded by General Archdale Wilson. Meanwhile reinforcements and siege artillery gradually arrived, and early in September it was resolved to make the assault. The first of the heavy batteries opened fire on the 8th September, and on the 13th a practicable breach was reported. On the morning of the 14th the assault was delivered, the points of attack being the Kashmir bastion, the water bastion, the Kashmir gate, and the Lahore gate. The assault was thoroughly successful, although the column which was to enter the city by the Lahore gate sustained a temporary check. The whole eastern part of the city was retaken, but at a loss of 66 officers and 1101 men killed or wounded, out of the total strength of 9866. Fighting continued more or less during the next six days, and it was not till the 20th September that the entire city and palace were occupied, and the reconquest of Delhi was complete. During the siege, the British force sustained a loss of 1012 officers and men killed, and 3837 wounded. Among the killed was General John Nicholson, the leader of one of the storming parties, who was shot through the body in the act of leading his men, in the first day's fighting. He lived, however, to learn that the whole city had been recaptured, and died on the 23d September. On the flight of the mutineers, the king and several members of the royal family took refuge at Humayun's tomb. On receiving a promise that his life would be spared, the last of the house of Timur surrendered to Major Hedson; he was afterwards banished to Rangoon. Delhi, thus reconquered, remained for some months under military authority. Owing to the murder of several European soldiers who strayed from the lines, the native population was expelled the city. Hindus were soon afterwards readmitted, but for some time Mahometans were rigorously excluded. Delhi was made over to the civil authorities in January 1858, but it was not till 1861 that the civil courts were regularly reopened. The shattered walls of

the Kashmir gateway, and the bastions of the northern face of the city, still bear the marks of the cannonade of September 1857. Since that date, Delhi has settled down into a prosperous commercial town, and a great railway centre. The lines which start from it to the north, south, east, and west bring into its bazaars the trade of many districts. But the romance of antiquity still lingers around it, and Delhi was selected for the scene of the Imperial Proclamation on the 1st January 1877.

An excellent chapter on Delhi will be found in Mr Keene's *Fall of the Moghul Empire*. In preparing the above account, the materials have been chiefly drawn from the official *Statistical Account of Delhi District*, together with Sir J. W. Kaye's *History of the Sepoy War* (W. W. H.)

DELIA, a festival of Apollo held in Delos. It included athletic and musical contests, for which the prize was a branch of the sacred palm. This festival was said to have been established by Theseus when returning from Crete. The Athenians took special interest in maintaining its splendour.

DELILLE, JACQUES (1738-1813), a French poet, was born on the 22d of June 1738, at Aiguës-Perso in Auvergne. He was an illegitimate child, and was connected by his mother with the family of the Chancellor de l'Hôpital. With very slender means of support he was educated at the college of Lisieux in Paris, and made such progress in his studies as augured well for his future distinction. When his education was completed, he was forced to accept of a very humble situation as elementary teacher in the college of Beauvais, but this was soon exchanged for the more honourable station of professor of humanity at Amiens. After returning to Paris, where he obtained a professorship at the Collège de la Marche, he speedily acquired a considerable poetical fame, which was greatly increased by the publication (1769) of his translation of the *Georgics* of Virgil, which he had begun at Amiens. Voltaire was greatly struck with the enterprise and the success of Delille; and without any personal acquaintance with the poet he, of his own accord, recommended him and his work to the good graces of the Academy. He was at once elected a member, but was not admitted until 1774 owing to the opposition of Richelieu, who alleged that he was too young. He now aimed at a higher distinction than even a finished translation of the most finished poem in the world could confer upon him; and in the *Jardins*, which he published in 1782, he made good his pretensions as an original poet. Before he had gone far in the composition of his next poem, which was not, indeed, published till after many of his other works, he made a journey to Constantinople in the train of the ambassador M. de Choiseul Gouffier. On his return to Paris he lectured, in his capacity of professor, on the Latin poets, and was attended by a numerous audience, who were delighted, not only with his critical observations, but with his beautiful recitation. Delille continued to advance in fame and fortune, though without hazarding any more publications, till the period of the Revolution, when he was reduced to poverty, and sheltered himself in retreat from the disasters which surrounded him. He quitted Paris, and retired to St Dié, the native place of Madame Delille; and here he completed, in deep solitude, his translation of the *Æneid*, which he had begun many years before. A residence in France, however, soon became very undesirable, and he emigrated first to Basle and then to Glarisse in Switzerland, a charming village on the Lake of Bièvre, opposite Rousseau's island of St Pierre. Much delighted with this enchanting country, and with the reception which he met from its inhabitants, he occupied himself constantly in the composition of poetry, and here finished his *Homme des Champs*, and his poem on the *Trois Règnes de la*

Nature. His next place of refuge was in Germany, where he composed his *La Pitié*, and finally, he passed two years in London, chiefly employed in translating *Paradise Lost*. In 1801, finding that he might return safely to Paris, he did so, carrying with him his immense *Poetical Encyclopædia*. He resumed his professorship and his chair at the Academy, but lived in retirement. His later poems were very numerous, but were not fitted to increase his reputation, which rests mainly on his translation of the *Georgics* and his *Jardins*. In his later years he became blind. He died on the 1st May 1813.

Delille left behind him little prose. His preface to the translation of the *Georgics* is an able essay, and contains many excellent hints on the art and difficulties of translation. He wrote the article "La Bruyère" in the *Biographie Universelle*. The following is the list of his poetical works:—*Les Géorgiques de Virgile, traduites en vers français*, Paris, 1769, 1782, 1785, 1809; *Les Jardins, en quatre chants*, 1780, new edition, London, 1800, Paris, 1802; *L'Homme des Champs, ou les Géorgiques Françaises*, 1800; *Poésies Fugitives*, 1802; *Dithyrambe sur l'Immortalité de l'Âme, suivi du passage du Saint Gothard*,—poème traduit de l'Anglais de Madame la Duchesse de Devonshire, 1802; *La Pitié*,—poème, en quatre chants, London and Paris, 1803; *L'Enéide de Virgile, traduite en vers français*, 1805; *L'Imagination*, poème en huit chants, 1806; *Les Trois Règles de la Nature*, 1809; *La Conversation*, 1812. A collection given under the title of *Poésies Diverses*, 1801, was disavowed by Delille.

DELIRIUM, a temporary disorder of the mind generally occurring in connection with some form of bodily disease. It may vary in intensity from slight and occasional wandering of the mind and incoherence of expression, to fixed delusions and violent maniacal excitement, and again it may be associated with more or less of coma or insensibility (see **MENTAL DISEASES**). Delirium is apt to occur in most diseases of an acute nature, such as fevers or inflammatory affections, in injuries affecting the brain, in blood diseases, in conditions of exhaustion, and as the result of the action of certain specific poisons, such as opium, Indian hemp, belladonna, chloroform, and alcohol. The form of delirium which is due to the action of the last-named substance is one of great importance from its comparative frequency, and is well known by the name of Delirium Tremens.

Delirium Tremens is one of a train of symptoms of what is termed in medical nomenclature acute alcoholism, or recent excessive indulgence in alcohol. It must, however, be observed that this disorder, although arising in this manner, rarely comes on as the result of a single debauch in a person unaccustomed to the abuse of stimulants, but generally occurs in cases where the nervous system has been already subjected for a length of time to the poisonous action of alcohol, so that the complaint might be more properly regarded as acute supervening on chronic alcoholism. It is equally to be borne in mind that many habitual drunkards never suffer from delirium tremens.

It was long supposed, and is indeed still believed by some, that delirium tremens only comes on when the supply of alcohol has been suddenly cut off; but this view is now generally rejected, and there is abundant evidence to show that the attack comes on while the patient is still continuing to drink. Even in those cases where several days have elapsed between the cessation from drinking and the seizure, it will be found that in the interval the premonitory symptoms of delirium tremens have shown themselves, one of which is aversion to drink as well as food—the attack being in most instances preceded by marked derangement of the digestive functions. Occasionally the attack is precipitated in persons predisposed to it by the occurrence of some acute disease, such as pneumonia, by accidents, such as burns, also by severe mental strain, and by the deprivation of food, even where the supply of alcohol is less than would have been likely to produce it otherwise. Where, on the other hand, the quantity of alcohol taken has been very large, the attack is sometimes ushered in

by fits of an epileptiform character. Males are much more frequently the subjects of delirium tremens than females.

One of the earliest indications of the approaching attack of delirium tremens is sleeplessness, any rest the patient may obtain being troubled by unpleasant or terrifying dreams. During the day there is observed a certain restlessness and irritability of manner, with trembling of the hands and a thick or tremulous articulation. The skin is perspiring, the countenance oppressed-looking and flushed, the pulse rapid and feeble, and there is evidence of considerable bodily prostration. These symptoms increase each day and night for a few days, and then the characteristic delirium is superadded. The patient is in a state of mental confusion, talks incessantly and incoherently, has a distressed and agitated or perplexed appearance, and a vague notion that he is pursued by some one seeking to injure him. His delusions are usually of transient character, but he is constantly troubled with visual hallucinations in the form of disagreeable animals or insects which he imagines he sees all about him. He looks suspiciously around him, turns over his pillows, and ransacks his bed-clothes for some fancied object he supposes to be concealed there. There is constant restlessness, a common form of delusion being that he is not in his own house, but imprisoned in some apartment from which he is anxious to escape to return home. In these circumstances he is ever wishing to get out of bed and out of doors, and, although in general he may be persuaded to return to bed, he is soon desiring to get up again. The trembling of the muscles from which the name of the disease is derived is a prominent but not invariable symptom. It is most marked in the muscles of the hands and arms and in the tongue. The character of the delirium is seldom wild or noisy, but is much more commonly a combination of busy restlessness and indefinite fear. When spoken to the patient can answer correctly enough, but immediately thereafter relapses into his former condition of incoherence. Occasionally maniacal symptoms develop themselves, the patient becoming dangerously violent, and the case thus assuming a much graver aspect than one of simple delirium tremens.

In most cases the symptoms undergo abatement in from three to six days, the cessation of the attack being marked by the occurrence of sound sleep, from which the patient awakes in his right mind, although in a state of great physical prostration, and in great measure if not entirely oblivious of his condition during his illness.

Although generally the termination of an attack of delirium tremens is in recovery, it occasionally proves fatal by the supervention of coma and convulsions, or acute mania, or by exhaustion, more especially when any acute bodily disease is associated with the attack. In certain instances delirium tremens is but the beginning of serious and permanent impairment of intellect, as is not unfrequently observed in confirmed drunkards who have suffered from frequent attacks of this disease.

The treatment of delirium tremens has given rise to much discussion among medical men, and the result has been that more rational views now prevail on the subject than formerly. This change is doubtless in great measure to be ascribed to the clearer ideas respecting the real nature and true cause of the malady which extensive and accurate observation has afforded. The theory once so widely accepted, that delirium tremens was the result of the too sudden breaking off from indulgence in alcohol, led to its treatment by regular and often large doses of stimulants, a practice fraught with mischievous results, since however much the delirium appeared to be thus calmed for the time, the continuous supply of the poison which was the original source of the disease inflicted serious damage upon the

brain, and led in many instances to the subsequent development of insanity. The former system of prescribing large doses of opium, with the view of procuring sleep at all hazards, was no less pernicious; and there is reason to fear that not a few cases of delirium tremens have ended in fatal coma from what was in reality opium poisoning. In addition to these methods of treatment, mechanical restraint of the patient was the common practice.

The views of the disease which now prevail, recognizing the delirium as the effect at once of the poisonous action of alcohol upon the brain and of the want of food, encourage reliance to be placed for its cure upon the entire withdrawal, in most instances, of stimulants, and the liberal administration of light nutriment, in addition to quietness and gentle but firm control, without mechanical restraint. In mild attacks this is frequently all that is required. In more severe cases, where there is great restlessness, sedatives have to be resorted to, and many substances have been recommended for the purpose. Opium administered in small quantity, and preferably by hypodermic injection, are undoubtedly of value; and chloral, either alone or in conjunction with bromide of potassium, often answers even better. Such remedies, however, should be administered with great caution, and only under medical supervision.

Stimulants may be called for where the delirium assumes the low or adynamic form, and the patient tends to sink from exhaustion, or when the attack is complicated with some other disease. Such cases are, however, in the highest degree exceptional, and do not affect the general principle of treatment already referred to, which inculcates the entire withdrawal of stimulants in the treatment of ordinary attacks of delirium tremens. (J. O. A.)

DELITZSCH, a town of Prussia, in the province of Saxony, at the head of a district in the department of Merseburg, situated on the Lober, an affluent of the Mulde, 12 miles north of Leipzig at a railway junction. Its public buildings comprise an old castle of the 14th century now used as a female penitentiary, one Roman Catholic and three Protestant churches, a normal college (*Schullehrerseminar*) established in 1873, and several other educational institutions. Besides *Kuhschwanz*, a peculiar kind of beer, it manufactures tobacco, cigars, shoes, and hosiery; and coal-mining is carried on in the neighbourhood. Originally a settlement of the Sorbian Wends, and in the 12th century part of the possessions of the bishops of Merseburg, Delitzsch ultimately passed to the Sachsen-Merseburg family, and on their extinction in 1738 was incorporated with Electoral Saxony. Ehrenberg, the famous naturalist, was born in the town in 1795. Population in 1875, 8235.

DELOLME, JEAN LOUIS (1740–1806), jurist and constitutional writer, was born at Geneva in 1740. He studied for the bar, and had entered on the profession of an advocate in his native town when he was obliged to emigrate on account of the publication of a pamphlet entitled *Examen de trois parts de droit*, which gave offence to the authorities of the town. He found an asylum in England, where he lived for several years on the meagre and precarious income derived from occasional contributions to various journals. He maintained an honourable independence, however, until 1775, when he found himself compelled to accept aid from a charitable society to enable him to return home. He died at Sewen, a village in the canton of Schwytz, on the 16th July 1806. During his exile Delolme made a careful study of the English constitution, the results of which he published in his *La Constitution de l'Angleterre* (Amsterdam, 1771), of which an enlarged and improved edition in English appeared in 1772, and was several times reprinted. The work excited

much interest as the production of a foreigner, and as containing many acute observations on the causes of the excellence of the English constitution as compared with that of other countries. It is, however, wanting in breadth of view, being written before the period when constitutional questions were treated in a philosophical manner. Several editions were published after the author's death, the latest being in 1853 by MacGregor. Delolme also wrote *A Parallel between the English Government and the former Government of Sweden* (1772), *A History of the Flagellants* (1782), based upon a work of Boileau's, *An Essay on the Union of Scotland and England* (1787), and one or two smaller works.

DELOS, now *Mikra Dili*, or Little Delos, to distinguish it from *Megali Dili*, or Great Delos, an island in the Ægean, the smallest but most famous of the Cyclades, and, according to the ancient belief, the spot round which the group arranged itself in a nearly circular form. It is a rugged mass of granite, about 12 square miles in extent, in 37° 23' N. lat. and 25° 17' E. long, about half a mile to the east of Megali Dili, or Rhencia, and two miles to the west of Myconos. Towards the centre it rises to its greatest height of 350 feet in the steep and rocky peak of Mount Cynthus, which, though overtopped by several eminences in the neighbouring islands, is very conspicuous from the surrounding sea. It is now completely destitute of trees, but it abounds with brushwood of lentisk and cistus, and here and there affords a patch of corn-land to the occasional sower from Myconos. Of the many traditions that were current among the ancient Greeks regarding the origin of Delos—or, as they sometimes named it, Asteria, Ortygia, Chlamydia, or Pyripile—the most popular describes it as struck from the bed of the sea by a dart of Neptune's trident, and drifting devious through the Ægean till moored by Jupiter as a refuge for his persecuted Latona. It was soon after flooded with the birth-radiance of Apollo and Diana, and became for ever sacred to these twin deities of light. The island first appears in history as an Ionian colony and the seat of a great Ionic festival to which the Athenians, among the rest, were accustomed annually to despatch a *Θεωπία*, or sacred ship, with a number of *Deliaists*, *Θεωποί*, or sacred delegates. In the 6th century B.C. the influence of the Delian Apollo was at its height; Polycrates of Samos dedicated the neighbouring island of Rhencia to his service, and Pisistratus of Athens caused all the area within sight of the temple to be cleared of the tombs by which its sanctity was impaired. About a hundred years afterwards, in the sixth year of the Peloponnesian war (426 B.C.), the Athenians instituted a more elaborate lustration, caused every tomb to be removed from the island, and established a law that ever after any one whose condition seemed to threaten its pollution by either birth or death should be at once conveyed from its shores. And even this was not accounted sufficient, for, in 422, they expelled all its secular inhabitants. After the overthrow of Corinth, in 146 B.C., the commercial element which had in all probability been present from the first in the religious gatherings, came prominently forward, and Delos became the central mart of the Ægean. In the Mithridatic war it was laid waste by Menophanes, the general of the Bithynian king, and it never recovered its former prosperity, though it is said that, under the Roman empire, 10,000 slaves were sometimes put up for sale in a single day. Hadrian attempted to found a city which was to bear the proud name of New Athens; but, when visited by Pausanias towards the close of the same century, the whole island was almost depopulated. It is now absolutely without a permanent inhabitant, though during the summer months a few shepherds cross over with their flocks from Myconos or Rhencia. As a religious centre it is replaced by Tenos.

Nature. His next place of refuge was in Germany, where he composed his *La Pitié*, and finally, he passed two years in London, chiefly employed in translating *Paradise Lost*. In 1801, finding that he might return safely to Paris, he did so, carrying with him his immense *Poetical Encyclopædia*. He resumed his professorship and his chair at the Academy, but lived in retirement. His later poems were very numerous, but were not fitted to increase his reputation, which rests mainly on his translation of the *Georgics* and his *Jardins*. In his later years he became blind. He died on the 1st May 1813.

Dehille left behind him little prose. His preface to the translation of the *Georgics* is an able essay, and contains many excellent hints on the art and difficulties of translation. He wrote the article "La Bruyère" in the *Biographie Universelle*. The following is the list of his poetical works—*Les Géorgiques de Virgile, traduites en vers français*, Paris, 1769, 1782, 1785, 1809, *Les Jardins*, en quatre chants, 1780, new edition, London, 1800, Paris, 1802, *L'Homme des Champs, ou les Géorgiques Françaises*, 1800, *Poésies Fugitives*, 1802, *Dithyrambe sur l'Immortalité de l'Âme, suivi du passage du Saint Gothard*,—poème traduit de l'Anglais de Madame la Duchesse de Devonshire, 1802, *La Pitié*,—poème, en quatre chants, London and Paris, 1803, *L'Enéide de Virgile, traduite en vers français*, 1805; *L'Imagination*, poème en huit chants, 1806; *Les Trois Règnes de la Nature*, 1809, *La Conversation*, 1812. A collection given under the title of *Poésies Diverses*, 1801, was disavowed by Delille.

DELIRIUM, a temporary disorder of the mind generally occurring in connection with some form of bodily disease. It may vary in intensity from slight and occasional wandering of the mind and incoherence of expression, to fixed delusions and violent maniacal excitement, and again it may be associated with more or less of coma or insensibility (see **MENTAL DISEASES**). Delirium is apt to occur in most diseases of an acute nature, such as fevers or inflammatory affections, in injuries affecting the brain, in blood diseases, in conditions of exhaustion, and as the result of the action of certain specific poisons, such as opium, Indian hemp, belladonna, chloroform, and alcohol. The form of delirium which is due to the action of the last-named substance is one of great importance from its comparative frequency, and is well known by the name of Delirium Tremens.

Delirium Tremens is one of a train of symptoms of what is termed in medical nomenclature acute alcoholism, or recent excessive indulgence in alcohol. It must, however, be observed that this disorder, although arising in this manner, rarely comes on as the result of a single debauch in a person unaccustomed to the abuse of stimulants, but generally occurs in cases where the nervous system has been already subjected for a length of time to the poisonous action of alcohol, so that the complaint might be more properly regarded as acute supervening on chronic alcoholism. It is equally to be borne in mind that many habitual drunkards never suffer from delirium tremens.

It was long supposed, and is indeed still believed by some, that delirium tremens only comes on when the supply of alcohol has been suddenly cut off, but this view is now generally rejected, and there is abundant evidence to show that the attack comes on while the patient is still continuing to drink. Even in those cases where several days have elapsed between the cessation from drinking and the seizure, it will be found that in the interval the premonitory symptoms of delirium tremens have shown themselves, one of which is aversion to drink as well as food—the attack being in most instances preceded by marked derangement of the digestive functions. Occasionally the attack is precipitated in persons predisposed to it by the occurrence of some acute disease, such as pneumonia, by accidents, such as burns, also by severe mental strain, and by the deprivation of food, even where the supply of alcohol is less than would have been likely to produce it otherwise. Where, on the other hand, the quantity of alcohol taken has been very large, the attack is sometimes ushered in

by fits of an epileptiform character. Males are much more frequently the subjects of delirium tremens than females.

One of the earliest indications of the approaching attack of delirium tremens is sleeplessness, any rest the patient may obtain being troubled by unpleasant or terrifying dreams. During the day there is observed a certain restlessness and irritability of manner, with trembling of the hands and a thick or tremulous articulation. The skin is perspiring, the countenance oppressed-looking and flushed, the pulse rapid and feeble, and there is evidence of considerable bodily prostration. These symptoms increase each day and night for a few days, and then the characteristic delirium is superadded. The patient is in a state of mental confusion, talks incessantly and incoherently, has a distressed and agitated or perplexed appearance, and a vague notion that he is pursued by some one seeking to injure him. His delusions are usually of transient character, but he is constantly troubled with visual hallucinations in the form of disagreeable animals or insects which he imagines he sees all about him. He looks suspiciously around him, turns over his pillows, and ransacks his bed-clothes for some fancied object he supposes to be concealed there. There is constant restlessness, a common form of delusion being that he is not in his own house, but imprisoned in some apartment from which he is anxious to escape to return home. In these circumstances he is ever wishing to get out of bed and out of doors, and, although in general he may be persuaded to return to bed, he is soon desiring to get up again. The trembling of the muscles from which the name of the disease is derived is a prominent but not invariable symptom. It is most marked in the muscles of the hands and arms and in the tongue. The character of the delirium is seldom wild or noisy, but is much more commonly a combination of busy restlessness and indefinite fear. When spoken to the patient can answer correctly enough, but immediately thereafter relapses into his former condition of incoherence. Occasionally maniacal symptoms develop themselves, the patient becoming dangerously violent, and the case thus assuming a much graver aspect than one of simple delirium tremens.

In most cases the symptoms undergo abatement in from three to six days, the cessation of the attack being marked by the occurrence of sound sleep, from which the patient awakes in his right mind, although in a state of great physical prostration, and in great measure if not entirely oblivious of his condition during his illness.

Although generally the termination of an attack of delirium tremens is in recovery, it occasionally proves fatal by the supervention of coma and convulsions, or acute mania, or by exhaustion, more especially when any acute bodily disease is associated with the attack. In certain instances delirium tremens is but the beginning of serious and permanent impairment of intellect, as is not unfrequently observed in confirmed drunkards who have suffered from frequent attacks of this disease.

The treatment of delirium tremens has given rise to much discussion among medical men, and the result has been that more rational views now prevail on the subject than formerly. This change is doubtless in great measure to be ascribed to the clearer ideas respecting the real nature and true cause of the malady which extensive and accurate observation has afforded. The theory once so widely accepted, that delirium tremens was the result of the too sudden breaking off from indulgence in alcohol, led to its treatment by regular and often large doses of stimulants, a practice fraught with mischievous results, since however much the delirium appeared to be thus calmed for the time, the continuous supply of the poison which was the original source of the disease inflicted serious damage upon the

brain, and led in many instances to the subsequent development of insanity. The former system of prescribing large doses of opium, with the view of procuring sleep at all hazards, was no less pernicious; and there is reason to fear that not a few cases of delirium tremens have ended in fatal coma from what was in reality opium poisoning. In addition to these methods of treatment, mechanical restraint of the patient was the common practice.

The views of the disease which now prevail, recognizing the delirium as the effect at once of the poisonous action of alcohol upon the brain and of the want of food, encourage reliance to be placed for its cure upon the entire withdrawal, in most instances, of stimulants, and the liberal administration of light nutriment, in addition to quietness and gentle but firm control, without mechanical restraint. In mild attacks this is frequently all that is required. In more severe cases, where there is great restlessness, sedatives have to be resorted to, and many substances have been recommended for the purpose. Opiates administered in small quantity, and preferably by hypodermic injection, are undoubtedly of value; and chloral, either alone or in conjunction with bromide of potassium, often answers even better. Such remedies, however, should be administered with great caution, and only under medical supervision.

Stimulants may be called for where the delirium assumes the low or adynamic form, and the patient tends to sink from exhaustion, or when the attack is complicated with some other disease. Such cases are, however, in the highest degree exceptional, and do not affect the general principle of treatment already referred to, which inculcates the entire withdrawal of stimulants in the treatment of ordinary attacks of delirium tremens. (J. O. A.)

DELITZSCH, a town of Prussia, in the province of Saxony, at the head of a district in the department of Merseburg, situated on the Lober, an affluent of the Mulde, 12 miles north of Leipzig at a railway junction. Its public buildings comprise an old castle of the 14th century now used as a female penitentiary, one Roman Catholic and three Protestant churches, a normal college (*Schullehrerseminar*) established in 1873, and several other educational institutions. Besides *Kulhschwanz*, a peculiar kind of beer, it manufactures tobacco, cigars, shoes, and hosiery; and coal-mining is carried on in the neighbourhood. Originally a settlement of the Sorbian Wends, and in the 12th century part of the possessions of the bishops of Merseburg, Delitzsch ultimately passed to the Sachsen-Merseburg family, and on their extinction in 1738 was incorporated with Electoral Saxony. Ehrenberg, the famous naturalist, was born in the town in 1795. Population in 1875, 8235.

DELOLME, JEAN LOUIS (1740–1806), jurist and constitutional writer, was born at Geneva in 1740. He studied for the bar, and had entered on the profession of an advocate in his native town when he was obliged to emigrate on account of the publication of a pamphlet entitled *Examen de trois parts de droit*, which gave offence to the authorities of the town. He found an asylum in England, where he lived for several years on the meagre and precarious income derived from occasional contributions to various journals. He maintained an honourable independence, however, until 1775, when he found himself compelled to accept aid from a charitable society to enable him to return home. He died at Sewen, a village in the canton of Schwytz, on the 16th July 1806. During his exile Delolme made a careful study of the English constitution, the results of which he published in his *La Constitution de l'Angleterre* (Amsterdam, 1771), of which an enlarged and improved edition in English appeared in 1772, and was several times reprinted. The work excited

much interest as the production of a foreigner, and as containing many acute observations on the causes of the excellence of the English constitution as compared with that of other countries. It is, however, wanting in breadth of view, being written before the period when constitutional questions were treated in a philosophical manner. Several editions were published after the author's death, the latest being in 1853 by MacGregor. Delolme also wrote *A Parallel between the English Government and the former Government of Sweden* (1772), *A History of the Flagellants* (1782), based upon a work of Boileau's, *An Essay on the Union of Scotland and England* (1787), and one or two smaller works.

DELOS, now *Mikra Dili*, or Little Delos, to distinguish it from *Megali Dili*, or Great Delos, an island in the Ægean, the smallest but most famous of the Cyclades, and, according to the ancient belief, the spot round which the group arranged itself in a nearly circular form. It is a rugged mass of granite, about 12 square miles in extent, in 37° 23' N. lat. and 25° 17' E. long., about half a mile to the east of Megali Dili, or Rheneia, and two miles to the west of Myconos. Towards the centre it rises to its greatest height of 350 feet in the steep and rocky peak of Mount Cynthus, which, though overtopped by several eminences in the neighbouring islands, is very conspicuous from the surrounding sea. It is now completely destitute of trees; but it abounds with brushwood of lentisk and cistus, and here and there affords a patch of corn-land to the occasional sower from Myconos. Of the many traditions that were current among the ancient Greeks regarding the origin of Delos—or, as they sometimes named it, Asteria, Ortygia, Chlamydia, or Pyrgule—the most popular describes it as struck from the bed of the sea by a dart of Neptune's trident, and drifting devious through the Ægean till moored by Jupiter as a refuge for his persecuted Latona. It was soon after flooded with the birth-radiance of Apollo and Diana, and became for ever sacred to these twin deities of light. The island first appears in history as an Ionian colony and the seat of a great Ionic festival to which the Athenians, among the rest, were accustomed annually to despatch a *Θεωρίς*, or sacred ship, with a number of Delians, *Θεωροί*, or sacred delegates. In the 6th century B.C. the influence of the Delian Apollo was at its height; Polykrates of Samos dedicated the neighbouring island of Rheneia to his service, and Pisistratus of Athens caused all the area within sight of the temple to be cleared of the tombs by which its sanctity was impaired. About a hundred years afterwards, in the sixth year of the Peloponnesian war (426 B.C.), the Athenians instituted a more elaborate institution, caused every tomb to be removed from the island, and established a law that ever after any one whose condition seemed to threaten its pollution by either birth or death should be at once conveyed from its shores. And even this was not accounted sufficient; for, in 422, they expelled all its secular inhabitants. After the overthrow of Corinth, in 146 B.C., the commercial element which had in all probability been present from the first in the religious gatherings, came prominently forward, and Delos became the central mart of the Ægean. In the Mithridatic war it was laid waste by Menophanes, the general of the Bithynian king; and it never recovered its former prosperity, though it is said that, under the Roman empire, 10,000 slaves were sometimes put up for sale in a single day. Hadrian attempted to found a city which was to bear the proud name of New Athens; but, when visited by Pausanias towards the close of the same century, the whole island was almost depopulated. It is now absolutely without a permanent inhabitant, though during the summer months a few shepherds cross over with their flocks from Myconos or Rheneia. As a religious centre it is replaced by Tenos

and as a commercial centre by the flourishing port of Syra. Besides the site of the chief settlement or city, the following are the spots of antiquarian interest which can still be identified—the temple of Apollo, a splendid building of the Doric order which, in the words of Mr Tozer, now forms “a confused heap of white marble fragments, columns, bases, and entablatures, lying indiscriminately together,” the portico erected by Philip of Macedon; the base (within the temple area) of the colossal statue dedicated to the Delian Apollo by the people of Naxos; a theatre of Parian marble on the slope of Mount Cynthus, a temple to Isis, further up the hill, which probably explains the myth of the connection between the brook Inopus and the Nile; the so-called “treasury” of Delos, an Ionic temple on the summit; and the circular tank or lake which supplied the water for the religious rites. The ordinary buildings on the island were constructed of native granite, but marble was imported for the nobler edifices, which were destined to serve as so many quarries to the mediæval builders of Constantinople and Venice.

See Leake, *Northern Greece*, Salher, “Histoire de l'Isle de Délos,” in *Mémoires de l'Académie des Inscriptions*, Schweick, *Deliacorum*, part 1 1825, Tozer, “Delos and Rheneia,” in *Academy*, 1875, Lebégue, *Recherches sur Délos*, Paris, 1870.

DE LOUTHERBOURG, PHILIP JAMES (1740–1812), an artist of remarkably versatile ability and interesting personality. He was born at Strasburg, 31st October 1740, where his father, the representative of a noble Polish family, practised miniature painting in a semi-amateur manner, but he spent the greater part of his life in London, where he was naturalized, and exerted a considerable influence on the scenery of the English stage, as well as on the artists of the following generation, Turner, Martin, &c.

Young De Louthembourg was intended for the Lutheran ministry, and was educated at the university of Strasburg. As the calling, however, was foreign to his nature, he insisted on being a painter, and placed himself under Vanloo in Paris. The result was the immediate and precocious development of extraordinary powers. Besides this triumph, and independently of it, he became a figure in the fashionable society of that day, and the friend of such men as Diderot, who had just then mainly contributed to make Gesner celebrated. He was elected into the French Academy below the age required by the law of the institution, and painted landscapes, sea-storms, battles, all of which had a celebrity above those of the specialists then working in Paris. By temperament whatever was extraordinary and sensational was attractive to him, and the *bizarre* appeared in all he did. His *début* was made by the exhibition of twelve pictures, including *Storm at Sunset*, *Night*, *Morning after Rain*; and when he painted common things, as a group of asses, he gave the picture such a fantastic title as—*Father and Mother, Little Fanfan, Aunt and Uncle à la Bretagne, Cousin Germain*, and the *Perruquier* of all the Family. In the next stage of his life we find him travelling in Switzerland, Germany, and Italy, distinguishing himself as much by mechanic inventions as by painting. One of those, constructed at his native city, was the wonder of the day, showing quite new effects produced in a model theatre. The exhibition of lights behind canvases representing the moon and stars, the illusory appearance of running water produced by clear blue sheets of metal and gauze, with loose threads of silver, and so on, were his devices. Charles Blanc says one of these curious models, called “*Le Séraphin*,” still existed in the Palais Royal at the date of publication of his work, *École Française*. Having repaired to London, De Louthembourg was employed by Garrick, who offered him £500 a year to apply his mechanisms to Drury Lane, and to superintend the scene-painting, which he did with complete success,

making a new era in the adjuncts of the stage. Garrick's own piece, the *Christmas Tale*, and the pantomime, 1781–2, introduced the novelties to the public, and the delight not only of the masses, but of Reynolds and the artists, was unbounded. The green trees gradually became russet, the moon rose and lit the edges of passing clouds, and all the world was captivated by effects we now take little notice of. A still greater triumph awaited him on his opening an entertainment he called the “*Eidophusicon*,” which showed the rise, progress, and result of a storm at sea—that which destroyed the great Indiaman, the “*Hulswell*,”—and the Fallen Angels raising the Palace of Pandemonium. De Louthembourg has been called the inventor of the panorama, but this honour does not belong to him, although it first appeared about the same time as the eidophusicon. The first panorama was painted and exhibited by Barker the elder.

All this mechanism did not in the least prevent De Louthembourg from painting. Lord Howe's Victory off Ushant, 1794, and other large naval pictures, were commissioned for Greenwich Hospital Gallery, where they still remain. His grandest work, the *Destruction of the Armada*, is one of the finest sea-fights ever realized on canvas. He painted also the *Great Fire of London*, and several historical works, one of these being the *Attack of the Combined Armies on Valenciennes*, 1793. He was made R.A., in addition to other distinctions, in 1781, shortly after which date we find an entirely new mental impulse taking possession of him. He joined Balsano, Comte de Cagliostro, and travelled about with this extraordinary person,—happily leaving him, however, before the priests in Rome condemned him to death. We do not hear that Mesmer had attracted De Louthembourg, or that the Revolution carried him away, nor do we find an exact record of his connection with Cagliostro; but there exists a pamphlet published in 1789, *A List of a few Cures performed by Mr and Mrs De Louthembourg without Medicine*, which relates some very remarkable examples of such cures. Cagliostro had led him to seek the philosopher's stone, but his success was frustrated by a female relative breaking in on his nocturnal experiments and destroying the crucible at the very moment of projection. He died 11th March 1812. His publications are few,—some sets of etchings, and *English Scenery*, 1805. His colour is hot and brown, which has injured his fame as a painter.

DELPHI, Δελφοί, a town of ancient Greece in the territory of Phocis, famous as the seat of the most important temple and oracle of Apollo. It was situated about six miles inland from the shores of the Corinthian Gulf, in a rugged and romantic glen, closed on the N. by the steep wall-like under-cliffs of Mount Parnassus known as the Phædrades, or Sliding Rocks, on the E. and W. by two minor ridges or spurs, and on the S. by the irregular heights of Mount Cirphus. Between the two mountains the Plerstus flowed from east to west, and opposite the town received the brooklet of the Castalian fountain, which rose in a deep gorge in the centre of the Parnassian cliff. The site of the ancient town is now occupied by the village of Castri, and the natural features of the scene have been somewhat altered by the earthquake of 1870; but the main points of interest can still be distinguished.

The principal building of Delphi was the temple of Apollo, which stood immediately under the shelter of the northern cliff. It appears to have been of the Doric order outside, and of the Ionic within. The front was built of Parian marble, and the sculptural decorations were extremely rich. One pediment was adorned with representations of Latona, Diana, Apollo, and the Setting Sun, and the other with Dionysus and the Thyiades; the eastern architrave was hung with gilded shields presented

by the Athenians from the spoils of Marathon, and the western with similar trophies taken by the Ætolians from the Gauls; while among the subjects of the metopes are mentioned Hercules slaying the Lernean Hydra, Bellerophon and the Chimæra, Zeus and Mimas, Pallas and Enceladus, and Dionysus and a Giant. In the *pronaos* were inscribed the maxims of the Seven Sages of Greece; in the *cella* was the sacred hearth with a perpetual fire and the *ὀμφαλός*, or navel-stone, which was supposed to mark the centre of the world; and in the *adytum* was the sacred tripod and the subterranean chamber from which the vapour of prophecy ascended. Of less important buildings may be mentioned the *Lesche*, or public hall, the walls of which were adorned with the works of Polygnotus and other master-pieces of ancient art; the theatre, where the musical contests connected with the Pythian games were held; the *Stadium*, of which there are still considerable remains; and, in the suburb of the same name, the *Pylæa*, or assembly hall of the Amphictyonic Council. The town was entered from the east by a road from Bœotia known as the Schiste, or Cloven Way, and from the west by the great Crissean road, which was used by the pilgrims who came from the Coriuthian Gulf, and by another which stretched north-west to Amphissa. These roads were regarded almost as the property of the temple, and shared in its sacredness; and each Amphictyonic state was bound to keep them in repair within its own boundaries. About seven miles to the north of the town, on the side of Mount Parnassus, was the famous Corycian cave, a large grotto in the limestone rock, which afforded the people of Delphi a refuge during the Persian invasion. It is now called in the district the *Sarant' Aulai*, or Forty Courts, and is said to be capable of holding 3000 people.

Of the origin of the Delphian oracle nothing is known. One legend told how the prophetic virtues of the site were discovered by a shepherd whose goats began to frisk about under the influence of the subterranean vapour; and another related how Apollo, after he had slain the great serpent Pytho on the spot, boarded a Cretan ship in the neighbouring gulf, and consecrated the crew to his service. It seems almost certain that the place was the seat of a religious establishment previous to its connection with the worship of Apollo; but its whole historic importance—which can hardly be over-estimated—is entirely due to this connection. The first temple of stone was reputed to have been built by the semi-mythical personages Trophonius and Agamedes. It was burned down in 548 B.C., but was soon after replaced by the building which has already been described. The contract for the work was taken by the Athenian family of the Alcæonids, who were at that time in exile from the tyranny of Hippias. They employed the architect Spintarus, and acquired great credit for the disinterested liberality with which they accomplished their task. The principal facts in the history of Delphi have already been narrated in the article *AMPHICTYONY* (vol. i. p. 772), where the reader will also find an account of the relation in which the temple stood to the states of Greece. It only remains to tell how the sanctuary and its treasures, which had been miraculously saved from the Persians and the Gauls, were put under contribution by Sulla for the payment of his soldiers; how Nero removed no fewer than 500 brazen images from the sacred precincts; and how Constantine the Great enriched his new city by the sacred tripods, the statues of the Heliconian Muses, the Apollo, and the celebrated Pan dedicated by the Greek cities after the conclusion of the war with the Medes. Julian afterwards sent Oribasius to restore the temple; but the oracle responded to the emperor's enthusiasm with nothing but a wail over the glory that had departed.

See Pausanias for a detailed description of the town in the second century of the Christian era; the *Ion* of Euripides for many interesting descriptions; and among modern works Wilster, *De religione et oraculo Apollinis Delphici*, Copenhagen, 1827; Hullmann, *Würdigung des Delphischen Orakels*, 1837; Gotte, *Das Delphische Orakel*, 1839; Curtius, *Anecdota Delphica*, 1843; Schliemann in *Allgemeine Zeitung*, 1874.

DELPHINIA, a festival of Apollo held annually on the 7th of the month Munychion (April) at Athens, where he was styled Delphimos. All that is known of the ceremonies is that a number of girls proceeded to his temple carrying suppliants' branches and seeking to propitiate Apollo, probably as a god having influence on the sea. It was at this time of year that navigation opened again after the storms of winter.

DELTA. See PHYSICAL GEOGRAPHY.

DELUC, JEAN ANDRÉ (1727–1817), geologist and meteorologist, born at Geneva, February 8, 1727, was descended from a family which had emigrated from Lucca and settled at Geneva in the 15th century. His father, François Deluc, was the author of some publications in refutation of Mandeville and other rationalistic writers, which are best known through Rousseau's humorous account of his ennui in reading them; and he gave his son an excellent education, chiefly in mathematics and natural science. On completing it he engaged in commerce, which principally occupied the first forty-six years of his life, without any other interruption than that which was occasioned by some journeys of business into the neighbouring countries, and a few scientific excursions among the Alps. During these, however, he collected by degrees, in conjunction with his brother Guillaume Antoine, a splendid museum of mineralogy and of natural history in general, which was afterwards increased by his nephew André Deluc. He at the same time took a prominent part in politics. In 1768 he was sent to Paris on an embassy to the Duc de Choiseul, whose friendship he succeeded in gaining. In 1770 he was nominated one of the Council of Two Hundred. Three years later unexpected reverses in business made it advisable for him to quit his native town, which he only revisited once for a few days. The change was welcome in so far as it set him entirely free for scientific pursuits, and it was with little regret that he removed to England in 1773. He was made a fellow of the Royal Society in the same year, and received the appointment of reader to Queen Charlotte, which he continued to hold for forty-four years, and which afforded him both leisure and a competent income. In the latter part of his life he obtained leave to make several tours in Switzerland, France, Holland, and Germany. In Germany he passed the six years from 1798 to 1804; and after his return he undertook a geological tour through England. When he was at Gottingen, in the beginning of his German tour, he received the compliment of being appointed honorary professor of geology in that university, but he never entered upon the active duties of a professorship. He was also a correspondent of the Academy of Sciences at Paris, and a member of several other scientific associations.

His favourite studies were geology and meteorology. The situation of his native country had naturally led him to contemplate the peculiarities of the earth's structure, and the properties of the atmosphere, as particularly displayed in mountainous countries, and as subservient to the measurement of heights. He inherited from his father a sincere veneration for the doctrines of Christianity, and a disposition to defend the Mosaic account of the creation against the criticism whose principal weapons were furnished by his favourite science. His royal patroness was most anxious to encourage and promote his labours in this field, and he was generally supposed to have had

great success in removing the objections which had been advanced by his antagonists against the comparatively recent formation of the present continents. According to Cuvier, he ranked among the first geologists of his age. His principal geological work, *Lettres physiques et morales sur l'histoire de la terre* (6 vols. 8vo, The Hague, 1778), was dedicated to Queen Charlotte. It dealt with the appearance of mountains and the antiquity of the human race, explained the six days of the Mosaic creation as so many epochs preceding the actual state of the globe, and attributes the deluge to the filling up of cavities supposed to have been left void in the interior of the earth. This attempt to reconcile religion and science, so often since repeated, was ingenious and for a time successful with most minds. The theory of the Mosaic days was maintained in one form or other by several later geologists of high repute, though it is scarcely now thought worth discussion by any to whom that title can justly be applied.

Deluc's original experiments relating to meteorology are more valuable to the natural philosopher than most of his geological work; and he discovered many facts of considerable importance relating to heat and moisture. He noticed the disappearance of heat in the thawing of ice about the same time that Black founded on it his ingenious hypothesis of latent heat. He ascertained that water was more dense about 40° Fahr. than at the temperature of freezing, expanding equally on each side of the maximum, and he was the originator of the theory afterward re-advanced by Dalton, that the quantity of aqueous vapour contained in any space is independent of the presence or density of the air, or of any other elastic fluid, though it appears difficult to reconcile this opinion with some of the experiments of Deluc's great rival, Saussure, a philosopher who, as he very candidly allows, made in many respects more rapid progress in hygrometry than himself. Deluc's comparative experiments on his own hygrometer and on Saussure's show only that both are imperfect; but it may be inferred from them that a mean between the two would in general approach much nearer to the natural scale than either taken separately. It appears also probable that Saussure's is rather less injured by time than Deluc's, which has been found to indicate an increasing amount of mean moisture every year.

Deluc was a man of warm feelings, and of gentle and obliging manners, and his literary and scientific merits, as well as his unremitting attention to the service of the queen, insured her respect and kindness. He saw her daily for many years, and in his last illness, which was long and painful, she shewed him repeated marks of benevolent regard. He died at Windsor on the 7th of November 1817.

A brief notice of his more important works, in addition to that mentioned above, will give a clear idea of the nature and range of his scientific activity. His *Recherches sur les modifications de l'Atmosphère* (2 vols. 4to, Geneva, 1772; 1 vols. 8vo, Par. 1784), contains many accurate and ingenious experiments upon moisture, evaporation, and the indications of hygrometers and thermometers, applied to the barometer employed in determining heights. In the *Phil. Trans.*, 1773, appeared his account of a new hygrometer, which resembled a mercurial thermometer, with an ivory bulb, which expanded by moisture, and caused the mercury to descend. The first correct rules ever published for measuring heights by the barometer were those he gave in the *Phil. Trans.*, 1771, p. 158. His *Lettres sur l'Histoire physique de la Terre* (8vo, Par. 1798) were addressed to Professor Blumenbach. The substance had already appeared in the *Journal de Physique*, for 1790, 1791, and 1798. The volume contains an essay written for a prize at Haarlem in 1791, but without success, on the existence of a General Principle of Morality. It also gives an interesting account of some conversations of the author with Voltaire and Rousseau. Deluc was an ardent admirer of Bacon, on whose writings he published two works,—*Bacon tel qu'il est* (8vo, Berlin, 1800), shewing the bad faith of the French translator, who had

omitted many passages favourable to revealed religion, and *Précis de la Philosophie de Bacon* (2 vols. 8vo, Paris, 1802), giving an interesting view of the progress of natural science. *Lettres sur le Christianisme* (Berlin and Hanover, 1801, 1803) was a controversial correspondence with Dr Teller of Berlin in regard to the Mosaic cosmogony. His *Traité élémentaire de Géologie* (8vo, Paris, 1800, also in English, by Delafite, the same year), was principally intended as a refutation of the Vulcanian system of Hutton and Playfair, who deduced the changes of the earth's structure from the operation of fire, and attributed a higher antiquity to the present state of the continents than is required in the Neptunian system adopted by Deluc after Dolomieu. He sent to the Royal Society, in 1809, a long paper on separating the chemical from the electrical effect of the pile, with a description of the electric column and aerial electroscope, in which he advanced opinions so little in unison with the latest discoveries of the day, that the council deemed it inexpedient to admit them into the *Transactions*. He had, indeed, on other occasions shown somewhat too much scepticism in the rejection of new facts; and he had never been convinced even of Cavendish's all-important discovery of the composition of water. The paper was afterwards published in Nicholson's *Journal* (xvi), and the dry column described in it was constructed by various experimental philosophers. Many other of his papers on subjects kindred to those already mentioned are to be found in the *Transactions* and in the *Philosophical Magazine*. See *Philosophical Magazine*, November 1817.

DELUGE, a submersion of the world, related by various nations as having taken place in a primitive age, and in which all, or nearly all, living beings are said to have perished. By this definition we exclude all partial floods, and also the theory which would account for deluge-stories as exaggerations of traditions of local inundations. Upon a low level of culture, as Von Hahn has shown, the memory of the most striking events is hardly preserved even for a few generations. It is best therefore to regard the story of the deluge as a subdivision of the primitive man's cosmogony. The problem with which he had to deal was a complicated one,—given the eternity of matter to account for the origin of the world. The best solution which presented itself (and that only to the shrewder races) was to represent creation as having taken place repeatedly, and the world as having passed through a series of demolitions and reconstructions. (See COSMOGONY). This explains the confusion between the creation and the deluge noticed by various travellers, e.g., among the Iroquois and the Santals—a confusion, however, which is only apparent, for the deluge is, when thoroughly realized, practically a second creation. Thus Manui the hero of the Indian flood-story, was, by permission of Brahma, the creator of the present human race. Noah is called by Arabic writers "the second Adam," and Manui might with as good a right be called the Noah of the Adam of New Zealand. We, in the adult age of the world, have renounced these mythical forms of expression, but we still retain much of the feeling which prompted them. The wonder of creation is even to us constantly renewed in spring; to primitive man it was renewed in a special sense in each of the great world-cycles of mythology. We may lay it down, then, as a canon at the outset, that the various deluge-stories must be viewed in combination, and explained on a common principle. At the same time we must be careful not to confound different "deposits" of tradition, and must regard primarily the earliest and most original forms of myths. As in the case of the cosmogonies, a few typical specimens will be all that can here be described.

I. Among the Semitic races the seniority belongs to the Babylonians. Till lately, the only version of their story known to us was that of Berossus (Muller, *Fragmenta*, n. 501), who relates that the god Krenos appeared to Xisuthrus, tenth king of Babylon [cf. Noah, tenth patriarch] in a dream, and warned him of the coming deluge. The details remind us a good deal of the biblical narrative, except that Xisuthrus is also accompanied by a steersman and by his near friends. Even the three repeated letting-out

of the birds is mentioned. At last the ship (as it is called) grounded "on a certain mountain," where Xisnthrus erected an altar and sacrificed; after which both he and his companions disappeared [cf. the "translation" of Enoch]. The duration of the deluge is not stated, and its cause is left to be inferred from the special commendation of Xisnthrus for his piety. Berossus has evidently drawn from cuneiform sources, but those sources have not yet been discovered. Our most valuable authority for the Babylonian deluge-story is the portion of the 11th lay of the great mythological epic, discovered by Mr George Smith. It came from the library of King Assurbanipal, and dates from about 660 B.C., but the Accadian original from which it was translated may well (says the cautious Assyriologist, Dr Schrader) have been composed between 1000 and 2000 B.C., while the myths themselves will of course be much older. The hero of the deluge bears the name of Tam-zi ("the sun of life," cf. Tammuz), for so, with Mr Sayce, the signs should most probably be read. He is called the son of Ubara-tutu, an Accadian name meaning "the splendour of sunset" (Lenormant, Sayce). This version of the story differs in several respects from that of Berossus. The deity who warns Tamzi is Hea (god of knowledge and of the waters), who orders him to build a ship, and to put into it his household and his wealth and the beasts of the field. All this is related by Tamzi to the (solar) hero "Izdubar." He tells how he coated the ship within and without with bitumen (cf. Gen. vi. 14), how he intrusted all to a "seaman," how Samas, the sun-god, and other gods (Hea is not now mentioned) sent rain, and how the rain-flood "destroyed all life from the face of the earth." (Why the deluge was sent is a little uncertain, owing to the mutilated condition of the tablets.) On the seventh day there was a calm, and the ship stranded on the mountain Nizir. Another seven days, and Tamzi let out "a dove" (?), then a swallow, both of which returned, and a raven which did not return. Then he left the ship and made a libation; Mr Smith's "altar" is uncertain. Finally, Hea intercedes with Bel that there be no second deluge, after which "Tamzi and his wife, and the people, were carried away to be like the gods." Such are the leading authentic features of the Babylonian narrative, or rather narratives, for its inconsistencies and repetitions are such as to force upon us the hypothesis that two documents originally existed, which have been welded together by an editor.

II. The Jewish narrative, like the Babylonian, has been thought to consist of two documents, an Elohistic and a Yahvistic, which have been connected by an editor. They appear to differ in various details,—e.g., in the duration of the flood (the Elohist extends it to a whole solar year), and in the description of the introduction of the animals into the ark (the Elohist alludes to the legal distinction between clean and unclean). But they have certainly the same origin, for they entirely coincide in the main outlines (e.g., in ascribing the flood to the depravity of mankind, in the mode of Noah's rescue, and in the promise that the catastrophe should not recur), and even in not a few expressions, among which are the names for the flood and the ark. They agree, further, in this important point, that some expressions point to a universal deluge, others to one which only affected a level inland region like that of Mesopotamia. We naturally ask, therefore, are the former involuntary exaggerations? or "survivals" of a primeval myth? Both views are held by respectable critics; but the latter is more favoured by analogy and by the remarkable parallelism between both the biblical narratives (especially the Yahvistic) and the Babylonian.

These two—the Babylonian and the Jewish—are the only fully developed deluge-stories told by any of the

Semitic nations. In what relation, then, do they stand to each other? Was the Babylonian borrowed from the Jewish (or from some earlier form of the story, of which the Jewish is an abridgment), or *vice versa*? On the one hand, the Babylonian story as a whole perhaps produces an impression of greater originality than the Jewish; for (not to mention other points) in the former the order in which the birds are sent out is much more natural. On the other, the "ark," or rather "chest," of the Jewish narrative sounds more archaic than the "ship" of the Babylonian. The word for "deluge" in Genesis is also evidently archaic, as appears from the facts that it only occurs once again (Psalm cxix. 3), and that the editor in Genesis needed to explain it by the word "water" (Gen. vi. 17, "the flood, viz., water"). It is possible, therefore, to hold that the Jewish story is a distinct offshoot of a common Semitic tradition. Bolder critics will maintain that the account in Genesis must be taken in connection with the other narratives which can be explained by, and are therefore possibly dependent upon, parallel Babylonian narratives. (See BABYLONIA and COSMOGONY). They will urge that "chest" may have been substituted for "ship" to avoid an anachronism, mankind in Noah's time not having perhaps reached the sea; and that the archaic word for "deluge" does not prove the antiquity of a developed deluge-story; also that there are traces in Genesis (see iv. 17–24, vi. 1–3) of another and presumably native Hebrew view, according to which the moral degeneration of man was explained without a deluge. The question is a large one, but may perhaps be reduced to this—Can the Yahvistic narrative in Genesis be safely broken up into several? There is some evidence, both internal and (see the prophetic references to Genesis) external to show that it can, but it would be premature in this place to pronounce whether the evidence is sufficient. It will hardly be possible, however, to derive the Yahvistic flood-story from Babylonian, and not the Elohistic, as has been suggested, for though the former is nearest to the Babylonian story (e.g., it ascribes the flood entirely to a rain-storm, whereas the latter introduces also the waters below the firmament), the latter agrees with it in all essential points, and even in the minor point of the bitumen. Let it be remarked in passing that, even if the material of the biblical narratives be taken from the Babylonian, the former have received a peculiar and original stamp, both by their monotheism and by the moral significance so emphatically given to the catastrophe, just as by the addition of the lovely story of the rainbow the Elohist has produced a conclusion far superior, artistically speaking, to that of his Babylonian predecessor.

III. Another of the great countries by which the Israelites might have been influenced was Egypt, but in this, even more than in a former, case a direct Egyptian influence is out of the question. The deluge-story was entirely unknown in the Nile-valley. It is commonly said, but erroneously, that this was owing to the absence of sudden catastrophes of the nature of an inundation. But if the terrestrial deluge is really (see below) only a transformation of the celestial, there is no reason why the story should not have grown up in Egypt, if the imagination of its inhabitants had invited such a development; for the germs of the deluge-story certainly existed in Egypt. The *Book of the Dead* constantly refers to the sun-god, Ra, as voyaging in a boat on the celestial ocean, and a story in an inscription of the archaic period (Seti I.) embodies a conception altogether analogous to that of the narrative in Genesis. According to this myth—which is described by M. Naville—Ra, the creator, being disgusted with the insolence of mankind, resolves to exterminate them. The massacre causes human blood to flow to Heliopolis,

of the sun are, to the primitive man, daily miracles. Hence the theory (Schirron and Gerland) that the deluge of the stories we are considering has been transferred from the sky to the earth, that it is in a word an ether-myth. This mode of explanation is not set aside by referring to quasi-historical details in the deluge-stories. For as soon as the mythic stage begins to be outgrown, rationalism appears. In this transitional period (commonly of long duration) the old nature-myths are modified. Some mythic elements remain, others are turned into prose. The attempt to explain the existence of the world on the basis of an ether-myth was an early symptom of the denaturalization of which we have spoken. At a still more advanced stage of the process, the flood often ceased to be universal, and was restricted to the home of those who related the story, or to the region from which they supposed themselves to have migrated. At last the shrewder intellects (e.g., among the Tahitians and some of the American Indians) even clutched at phenomena like those of fossil-shells found on hills to prove the literal truth of their deluge.

The most plausible arguments for the celestial deluge-theory are derived from the Polynesian mythology. In the flood-story of Raiatea, given by Ellis (*Polynesian Researches*, ii. 58-9), the flood rose "as the sun approached the horizon;" and the island where the fisherman found refuge is called Toa-marama, i.e., moon-tree (tree reaching up into the moon), which reminds us of the Tentonic world-ash-tree, Yggdrasil, and the mythic mountain of the Babylonians (see below) and other nations. At Hawaii the flood was even called "flood of the moon," and at New Zealand "flood of day's eye" (i.e., the sun). Schirren explains all these myths as pictures of sunset, just as he derives the cosmogonies from myths of sunrise. But most of them are more easily explained, with Gerland, as ether-myths. The sun and moon were imagined as peaks emerging out of a flood—sometimes as canoes, sometimes as a man and his wife—the sole survivors (except perhaps the stars, their children) from the inundation. There was, however, no fixity of meaning. The stars were sometimes regarded as ships, but so too were the clouds, "Tangalon's ships." The Babylonian story, as represented in the 11th Izdubar lay, suggests a similar theory. The names of the hero and his father mean "the (morning) sun" and "the evening-glow." The flood is a rain-flood, and the "father of the rain" (cf. Job xxxviii. 28) is the celestial ocean, which in the original myth must have been itself the deluge; and the "ship" is like that in which the Egyptian sun-god voyages in the sea of ether. The mountain on which the survivors come to land was originally (as in Polynesia) the great mythic mountain (cf. the Accadian *Kharsak Lurra*, "mountain of the east"), which joins the sky to the earth, and serves as an axis to the celestial vault. Traces of an ether-myth have also been discovered in the Indian deluge-story, as indeed is only natural if it be based on the Babylonian. In the *Mahābhārata*, the divine fish has a horn issuing from his head, which reminds us of other horned deities, whose solar origin is admitted, such as Baal and the Berosian Oannes. (See also Schirron, *Wanderungen der Neuseeländer*, p. 193, who is, however, too fanciful to be a safe guide).

Two points should be mentioned in conclusion. (1.) Though a moral significance is by no means always attributed to the deluge, it is more common than might have been expected. In the *Mahābhārata* (line 12,774) it takes the form not of retribution but of purification, which agrees with Plato's view (*Timæus*, p. 22). We find it in America among the Quichés, but this may perhaps be a later addition, as is certainly the case in one of the forms of the Tahitian myth (Waitz, vi. 271). And (2.) the deluge is not always the last of those periodical

destructions alluded to at the beginning of this article. A few races suppose the last link in the series to be a great fire which swept every living thing from the earth, except (as some American Indians say) a few who took refuge in a deep cave. This last feature, however, has a slightly suspicious resemblance to Gen. xix. 29, and, to say the least, the conflagration is not a myth of such proved antiquity and spontaneity as the deluge. It is too suggestive of artificial systems like that of the Stoics.

Authorities—Babylonian story: Mr. George Smith's papers in *Transactions of Biblical Archaeological Soc.*, ii. 213-34, iii. 530-96, Lenormant, *Les premières civilisations*, tom. ii. 3-146; Dehtzsch, *George Smith's Chald. Genesis*, 318-21. Biblical narrative: Commentaries on Genesis, by Knobel and Dillmann, Dehtzsch, Kabisch; Ewald, *Biblische Jahrbücher*, vi. 1-23. DEMADES, an orator and demagogue who flourished in the 4th century B.C. He was originally of humble position, and was employed at one time as a common sailor, but he rose partly by his eloquence and partly by his unscrupulous character to a prominent position at Athens. He espoused the cause of Philip in the war against Olynthus, and was thus brought into bitter and life-long enmity with Demosthenes. Notwithstanding his sympathies he fought against the Macedonians in the battle of Cheronæa, after which he was instrumental in procuring a treaty of peace between Macedon and Athens through his influence with Philip. He continued to be a favourite of Alexander, and, prompted by a bribe, saved Demosthenes and the other obnoxious Athenian orators from his vengeance. His conduct in supporting the Macedonian cause, yet receiving any bribes that were offered by the opposite party, caused him to be heavily fined more than once, and his flagrant disregard of law and honour ultimately led the citizens of Athens to pass upon him the sentence of atimia. This was recalled in 322 on the approach of Antipater, to whom the citizens sent Demades and Phocion as ambassadors. Before setting out he persuaded the citizens to pass sentence of death upon Demosthenes and his followers who had fled from Athens. Harpalus and Antipater both succeeded in bribing him to their cause, but the latter, discovering while Demades was with him on another embassy in 318 a correspondence which showed him to have been at the same time in communication with Perdicas, put him to death along with his son Demas. A fragment of a speech bearing his name is to be found in the *Oratores Attici*, but its genuineness is exceedingly doubtful.

DEMERARA, or DEMERARY, a river and county of British Guiana. See GUIANA.

DEMETER. See CERES, vol. v. p. 345.

DEMETRIA, a festival in honour of Demeter, held at seed-time, and lasting ten days. It appears to be the same as that generally called *Thesmophoria*.

DEMETRIUS I., king of Macedonia, a son of Antigonus and Stratonicæ, surnamed *Poliorcetes*, or the Besieger. Both father and son play an important part in the vicissitudes of the Macedonian empire after the death of Alexander the Great. Demetrius grew up to be a beautiful young man, reared in the fulness of the new Macedonian life, devoted to Greek science, and inspired with an eager ambition to rival the ancient heroes of his race. He united with these lofty aims a love of Oriental magnificence which formed at once the chief splendour and the principal weak-

ness of his Macedonian prototype. At the age of twenty-two he was sent by his father against Ptolemy, who had invaded Syria; he was totally defeated near Gaza, but soon repaired his loss by a victory which he obtained over Ciltes, in the neighborhood of Myus. After conducting an expedition against Babylon, and engaging in several campaigns against Ptolemy on the coasts of Cilicia and Cyprus, Demetrius sailed with a fleet of 250 ships to Athens, and restored the Athenians to liberty, by freeing them from the power of Cassander and Ptolemy, and expelling the garrison which had been stationed there under Demetrius Phalereus. After this successful expedition he besieged and took Munychia, and defeated Cassander at Thermopylae. His reception at Athens, after these victories, was attended with the greatest servility; and under the title of "The Preserver" the Athenians worshipped him as a tutelary deity. In the next campaign he defeated Menelaus by land, and completely destroyed the naval power of Ptolemy. After an interval spent at Cyprus, he endeavoured to punish the Rhodians for having deserted his cause; and his ingenuity in devising new instruments of siege, in his unsuccessful attempt to reduce the capital, gained him the appellation of Poliorcetes. He returned a second time to Greece as liberator. But traces of Oriental despotism showed themselves, and the licentiousness and extravagance of Demetrius made the Athenians regret the government of Cassander. He soon, however, roused the jealousy of the successors of Alexander; and Seleucus, Cassander, and Lysimachus united to destroy Antigonus and his son. The hostile armies met at Ipsus, 301 B.C. Antigonus was killed in the battle, and Demetrius, after sustaining a severe loss, retired to Ephesus. This reverse of fortune raised him many enemies; and the Athenians, who had lately adored him as a god, refused even to admit him into their city. But he soon afterwards ravaged the territory of Lysimachus, and effected a reconciliation with Seleucus, to whom he gave his daughter Stratonice in marriage. Athens was at this time oppressed by the tyranny of Cassander; but Demetrius, after a protracted blockade, gained possession of the city, and pardoned the inhabitants their former misconduct. The loss of his possessions in Asia recalled him from Greece; and he established himself on the throne of Macedonia by the murder of Alexander, the son of Cassander, 294 B.C. But here he was continually threatened by Pyrrhus, who took advantage of his occasional absence to ravage the defenceless part of his kingdom; and at length the combined forces of Pyrrhus, Ptolemy, and Lysimachus, assisted by the disaffected among his own subjects, obliged him to leave Macedonia after he had sat on the throne for seven years. He passed into Asia, and attacked some of the provinces of Lysimachus with varying success; but famine and pestilence destroyed the greater part of his army, and he retired to the court of Seleucus to seek support and assistance. Here he met with a kind reception; but, nevertheless, hostilities soon broke out; and after he had gained some advantages over his son-in-law, Demetrius was totally forsaken by his troops in the field of battle, and became an easy prey to the enemy. His son Antigonus offered Seleucus all his possessions, and even his person, in order to procure his father's liberty; but all proved unavailing, and Demetrius died in the fifty-fourth year of his age, after a confinement of three years, 284 B.C. His remains were given to Antigonus, honoured with a splendid funeral at Corinth, and thence conveyed to Demetrias. His posterity remained in possession of the Macedonian throne till the time of Perseus, who was conquered by the Romans. See MACEDONIA.

DEMETRIUS II., king of Macedonia, son of Antigonus Gonatas, who was a son of Demetrius Poliorcetes. He

occupied the throne for ten years, but little is known of him. His reign coincided with the period of the Achaean league, which was then strengthened by an alliance with the Cretolians. Only a fragment of Macedonian power remained in Greece; a few towns in the Peloponnese were held by Macedonian governors. Demetrius offered a slight opposition to the two patriotic leagues, and wrested Boeotia from the Cretolians. At his death in 232 B.C. Antigonus Doson undertook the government for his son Philip, who was under age.

DEMETRIUS I., named *Soter*, king of Syria, was sent to Rome as a hostage during the reign of Antiochus Epiphanes. He contrived, however, to escape from confinement, partly through the assistance of the historian Polybius, and established himself on the throne. He acquired his surname from the Babylonians on account of the expulsion of Heraclides from their capital, and is famous in Jewish history for his contests with the Maccabees. Demetrius fell in battle against the usurper Balas, about 150 B.C.

DEMETRIUS II., surnamed *Nicator*, the son of the preceding, lived in exile during the usurpation of Balas. At the head of a body of Cretan mercenaries, and with the assistance of Ptolemy Philometor, whose daughter he married, he regained the throne of Syria. His cruelties and vices, however, ultimately procured his expulsion from the kingdom; and Antiochus, the infant son of Balas, was proclaimed king in his stead. After ten years' captivity in Parthia he succeeded in establishing himself once more upon the throne; but his wife Cleopatra, indignant at his subsequent marriage with a daughter of the Parthian king, procured his assassination (126 B.C.).

DEMETRIUS III., called *Euergetes*, also *Euergetes* and *Philometor*, king of Syria, was the fourth son of Antiochus Grypus. By the assistance of Ptolemy Lathyrus he recovered part of his Syrian dominions from Antiochus Eusebes, and held his court at Damascus. He assisted the Jews against Alexander Jannæus. In attempting to dethrone his brother Philip he was defeated by the Arabs and Parthians and taken prisoner. He was kept in confinement in Parthia by king Mithridates until his death.

DEMETRIUS, an orator and Peripatetic philosopher, surnamed *Phalereus*, from the Attic demos of Phalerus, where he was born. He was the son of a poor man named Phanostatus, and was a scholar of Theophrastus. He governed the city of Athens as representative of Cassander for ten years, and 360 statues were erected to his honour. On the restoration of the old democracy by Demetrius Poliorcetes, he was obliged to leave the city, and escaped into Egypt, where he was protected by Ptolemy Lagos. This king, it is said, having asked his advice concerning the succession of his children to the throne, was advised by Demetrius to leave his crown to the children of Eurydice, rather than to Philadelphus, the son of Berenice. This displeased Philadelphus so much, that when his father died he banished Demetrius; and the unfortunate exile put an end to his life by the poison of an asp (282 B.C.). Demetrius composed more works in prose and verse than any other Peripatetic of his time. His writings treated principally of poetry, history, politics, rhetoric, and accounts of embassies; but none are extant. The treatise *περί ἐμπνεύσεως*, which is often ascribed to him, is probably the work of a later Alexandrian of the same name.

DEMETRIUS, a Cynic philosopher, was a disciple of Apollonius of Tyana, to whom he afterwards proved an able antagonist. He spent the greater part of his life at Corinth, and first became famous during the reign of Caligula. The emperor, wishing to gain the philosopher to his interest, sent him a large present; but Demetrius refused it with indignation, and said, "If Caligula wishes to bribe me, let him send me his crown." Vespasian was

displeased with his insolence, and banished him; but the Cynic derided the punishment, and bitterly inveighed against the emperor. He lived to an advanced age; and Seneca observes that nature had brought him forth to show mankind how an exalted genius may live uncorrupted by the vices of the world.

DEMETRIUS, or DMITRI. See RUSSIA.

DEMIDOFF, a Russian family honourably distinguished in various ways in the history of their country.

I. DEMIDOFF, NIKITA, the founder of the family, originally a blacksmith serf, was born about 1665. His skill in the manufacture of arms won him notoriety and fortune; and an iron foundry which he established for the Government became another source of wealth to him. Peter the Great, with whom he was a favourite, ennobled him in 1720.

II. DEMIDOFF, AKINFII, son of the former, greatly increased the wealth he had inherited by the discovery (along with his son) of gold, silver, and copper mines, which they worked with permission of the Government for their own profit. He died about 1740.

III. DEMIDOFF, PAUL GRIGORJEVICH, nephew of the preceding (born in 1738, died in 1821), was a great traveller, and devoted himself to scientific studies, the prosecution of which among his countrymen he encouraged by the establishment of professorships, lyceums, and museums. He founded the annual prize of 5000 roubles, adjudged by the Academy of Sciences to the author of the most valuable contribution to Russian literature.

IV. DEMIDOFF, NIKOLAY NIKITICH, nephew of the preceding, was born in 1774, and died at Florence in 1828. During the invasion of Napoleon he commanded a regiment equipped at his own expense. He also greatly increased his resources as a capitalist by successful mining operations, and like his uncle used his wealth to multiply facilities for the scientific culture of the inhabitants of Moscow. The erection of four bridges at St Petersburg was mainly due to his liberality. In 1830 a collection of his pamphlets, *Opuscules d'Économie Politique et Privée*, was published at Paris.

V. DEMIDOFF, ANATOLI, son of Paul, was born at Florence in 1812, and died at Paris in 1870. Educated in France, his life was chiefly spent in that country and in Italy. After his marriage with the daughter of Jerome Bonaparte, he lost for a time the favour of the Emperor Nicholas on account of provision having been made in the contract for the education of his children as Roman Catholics. During the Crimean war he was a member of the Russian diplomatic staff at Vienna. Like other members of his house, he expended large sums to promote education and to ameliorate the physical condition of his fellows. His munificence as a patron of art gave him European celebrity. The superb work, *Voyage dans la Russie méridionale et la Crimée, par la Hongrie, la Valachie, et la Moldavie*, was conjointly written and illustrated by him and the French scholars and artists who accompanied him. It has been translated into several European languages; the English version was published in 1853.

DEMISE. See LEASE.

DEMMIN, a town of Prussia, at the head of a circle in the government of Stettin, is situated on the Peene, which in the immediate neighbourhood receives the Trebel and the Tolleuse, 72 miles W.N.W. of Stettin. It has manufactures of woollen cloths, linens, hats, and hosiery, besides breweries, distilleries, and tanneries, and an active trade in corn and timber. Demmin is a town of Slavonian origin and of considerable antiquity, and was a place of importance in the time of Charlemagne. It was besieged by a German army in 1148, and captured by Henry the Lion in 1164. In the Thirty Years' War it was the object of frequent conflicts, and even after the Peace of Westphalia was taken

and retaken in the contest between the electoral prince and the Swedes. It passed to Prussia in 1720, and its fortifications were destroyed in 1759. In 1807 several engagements took place in the vicinity between the French and Russians. Population in 1875, 9856.

DEMOCRITUS, one of the founders of the Atomic philosophy, was born at Abdera, a Thracian colony, the inhabitants of which were notorious for their stupidity. Nearly all the information that we possess concerning his life consists of traditions of very doubtful authenticity. He was a contemporary of Socrates, but the date of his birth has been fixed variously from 494 to 460 B.C. His father (who is called by no less than three names) was a man of such wealth as to be able to entertain Xerxes and his army on their return home after the battle of Salamis. On coming into his inheritance, Democritus, there is good reason to believe, devoted several years to travel. He visited the East, and is supposed with great probability to have spent a considerable time in Egypt. The intensity of his thinking was figured by the ancients in the story that he put out his eyes in order that he might not be diverted from his meditations. But of the way in which he obtained the vast learning for which he was famed, and of his intercourse with other philosophers, even with Leucippus, we have no certain information. According to one very doubtful tradition, he was so honoured in his native city that, his patrimony being all spent, the incredible sum of 500 talents was voted him by his fellow-citizens, together with the honour of a public funeral; but, according to another tradition, his countrymen regarded him as a lunatic and sent for Hippocrates to cure him. All are agreed that he lived to a great age, Diodorus Siculus states that he was ninety at his death, and others assert that he was nearly twenty years older. He left, according to Diogenes Laertius, no less than 72 works, treating of almost every subject studied in his time, and written in Ionic Greek, in a style which for poetic beauty Cicero deemed worthy of comparison with that of Plato. But of all these works nothing has come down to us beyond small fragments.

The cosmical theory propounded by Democritus—which in part at least was adopted from the doctrines of Leucippus—is of all the materialistic explanations of the universe put forth by the Greeks the one which has held the most permanent place in philosophical thought. All that exists is vacuum and atoms. The atoms are the ultimate material of all things, including spirit. They are uncreated, and have existed from eternity. They are invisible, but extended, heavy, and impenetrable. They vary in shape, though whether Democritus held that they vary also in density is debated. And, lastly, these atoms are in motion. This motion, like the atoms themselves, Democritus held to be eternal. According to some, he explained it as caused by the downward fall of the heavier atoms through the lighter, by which means a lateral whirling motion was produced; but whether this explanation was given by Democritus is extremely doubtful. Another principle also is said by some to have been used by Democritus to explain the concurrence of the atoms in certain ways, viz., that there is an innate necessity by which similar atoms come together. However this may be, he did declare that by the motion of the atoms the world was produced with all that it contains.

Soul and fire are of one nature; the atoms of which they consist are small, smooth, and round, and it is by inhaling and exhaling such atoms that life is maintained. It follows that the soul perishes with, and in the same sense as, the body. There is, in fact, no distinction made between the principle of life and the higher mental faculties.

The Atomic theory of perception was as follows. From

every object εἰδωλα (or images) of the object are continually being given off in all directions, these enter the organs of sense, and give rise to sensation. The rest of the theory remarkably anticipates certain famous modern theories of perception (1) by its reduction of all sensation, on the objective side, to touch, and (2) by the distinction which it involves between the qualities of extension and resistance, which are said to be the only qualities that really belong to objects of sense, and the other (or secondary) qualities, which are said to exist only through the action of the organs of sense modifying the εἰδωλα.

Sensation, Democritus appears to have taught, is our only source or faculty of knowledge; indeed his first principles admit the existence of no mental faculty of a nature distinct from sensation. He was classed among the most extreme sceptics of antiquity, and tradition attributes to him such sayings as—"There is nothing true, and if there is, we do not know it," "We know nothing, not even if there is anything to know."

The system of Democritus was altogether anti-theological. He denied that the creation of the world was in any way due to reason. He also rejected all the popular mythology; but, according to one account, he taught that, as men were produced by the motion of the atoms, so was produced a race of grander beings, of similar form, and, though long-lived, still mortal, who influence human affairs, some benevolently, some malevolently, and who appear to men in dreams.

The moral system of Democritus is strikingly like the negative side of the system of Epicurus. The *summum bonum* is placed in an even tranquillity of mind. Fear, and too strong desire, and all that is likely to bring sorrow or even care, are to be avoided, as, for example, notably marriage, to which Democritus cherished the strongest objections. This habit of mind Democritus is said to have himself so well attained that the merry spirit with which he regarded all that happened earned him the title of "the laughing philosopher." Another version, however, asserts that he received the name on account of the scorn which he poured on human ignorance and weakness.

DEMOIVRE, ABRAHAM (1667-1754), an eminent mathematician, was born at Vitry, in Champagne, May 26, 1667. He belonged to a French Protestant family, and was compelled to take refuge in England at the revocation of the Edict of Nantes, in 1685. Having laid the foundation of his mathematical studies in France, he prosecuted them further in London, where he read public lectures on natural philosophy for his support. The *Principia Mathematica* of Newton, which chance threw in his way, made him comprehend at once how little he had advanced in the science which he professed, but he pursued his studies with vigour, and soon became distinguished among first-rate mathematicians. He was among the intimate personal friends of Newton, and his eminence and abilities secured his admission into the Royal Society of London, and afterwards into the Academies of Berlin and Paris. His merit was so well known and acknowledged by the Royal Society that they judged him a fit person to decide the famous contest between Newton and Leibnitz. The life of Demoivre was quiet and uneventful. His old age was spent in obscure poverty, his friends and associates having nearly all passed away before him. He died at London, November 27, 1754. The *Philosophical Transactions* of London

contain several of his papers, all of them interesting. He also published some excellent works, such as *Miscellanea Analytica de Seriebus et Quadraturis*, 1730, in 4to. This then contained some elegant and valuable improvements on then existing methods, which have themselves, however, long been superseded. But he has been more generally known by his *Doctrine of Chances*, or *Method of Calculating the Probabilities of Events at Play*. This work was first printed in 1618, in 4to, and dedicated to Sir Isaac Newton. It was reprinted in 1738, with great alterations and improvements, and a third edition was afterwards published with additions. He also published a *Treatise on Annuities*, 1724, in 8vo, dedicated to Lord Carpenter.

DEMONOLOGY. The word *demon* (or *dæmon*) is the Greek δαίμων, the etymology of which is too doubtful to explain its original signification (see Pott, *Etym. Forsch.*, ii. 1, 947). Setting aside the use of the word in the general sense of deity (as in *Iliad*, i. 222), we find it employed in classic Greek literature with the more specific meaning under which it becomes an important term in the science of religion. Among the most instructive passages are those in which Hesiod tells how the men of the golden race became after death demons, guardians or watchers over mortals (Hesiod, *Op. et Dies*, 109, &c.; see Weleker, *Griech. Gotterlehre*, vol. i. p. 731), and where the doctrines of Empedocles, Plato, and other philosophers are set forth, showing how the demons came to be defined as good and evil beings intermediate between gods and men (Plutarch, *De Defect. Orac.*, *De Isid. et Osir.*, *De Vitand. Æt. Alien.*, &c., Plato, *Symposium*, 28, Diog. Laert., *Vit. Pythag.*; see Grote, *History of Greece*, vol. i. chaps. 2, 17). The religions of the world usually recognize an order of spiritual beings, below the rank of governing deities, and distinguished from nature-spirits such as elves and nymphs by being especially concerned with living men and their affairs; these beings, very often themselves considered to be ghosts of dead men, are the demons. The earlier and wider notion of demons includes the whole class of such spirits, who may be friendly or hostile, good or evil, persecuting and tormenting man or acting as his protecting and informing patron-spirits, while, when they are mediators or ministers of some higher deity, they will be, like the god himself, kindly or ill-disposed. A narrower definition was introduced in Christian theology, where the ideas of a good demon and guardian genius were merged in the general conception of good "angels," while the term demon was appropriated to evil spirits, or "devils." For scientific purposes, it is desirable to use the term in the wider sense. Demonology, the branch of the science of religion which relates to demons, is much obscured in the treatises of old writers by their taking the evidence too exclusively from among civilized nations, and neglecting what is to be learnt from barbarous tribes, whose ideas of demons, being nearer their primitive state, are comparatively clear and comprehensible. When savage notions of the nature and functions of these spirits are taken as the starting-point, the demon appears as only a more or less modified human soul—whether it is still actually considered to be a human ghost, or whether part of the human quality has fallen away, so that only traces are left to show that man's soul furnished the original model. But when such early and natural animistic conceptions were carried on into higher stages of culture, their original use as explaining natural phenomena was gradually superseded by the growth of knowledge, and they came to be maintained as broken-down and confused superstitions, only to be understood by comparison with their earlier forms. Such comparison, however, is facilitated by the primitive demon-ideas cropping up anew even in civilized life, as in the so-called "spirit-manifestations" of the present day. The following details will show the main

purposes which the doctrine of demons served in the philosophy of the primitive and savage world, as well as its large contribution to civilized superstition. The authorities, when not mentioned, will mostly be found referred to in Tylor, *Primitive Culture*, chaps. xiv xv. Other cases are given in Spencer, *Principles of Sociology*, vol i., and every reader may supplement them with similar instances from the works of travellers and missionaries. Prof Adolf Bastian's *Der Mensch in der Geschichte* and *Beiträge zur Vergleichenden Psychologie* are of great value to students.

Among races of low culture, the conception of a ghost-soul being made to account for the phenomena of life (see article ANIMISM) readily leads to a corresponding theory of morbid states of body and mind. As the man's proper soul causes the functions of normal life by its presence, while its more or less continued absence induces sleep, trance, and at last death, so the abnormal phenomena of disease have a sufficient explanation at hand in the idea that some other soul or soul-like spirit is acting on or has entered into the patient. Among the cases which most strongly suggest this are—first, such derangements as hysteria, epilepsy, and madness, where the raving and convulsions seem to bystanders like the acts of some other being in possession of the patient's body and even the patient is apt to think so when he "comes to himself," and, second, internal diseases where severe pain or wasting away may be ascribed to some unseen being wounding or gnawing within. The applicability of demoniacal possession as a theory to explain disease in general is best proved by the fact that it is so often thus applied by savage races. Especially, reasoning out the matter in similar ways, rude tribes in different countries have repeatedly arrived at the conclusion that diseases are caused by the surviving souls or ghosts of the dead, who appear to the living in dreams and visions, thus proving at once their existence after death, and their continued concern with mankind. This notion being once set on foot, it becomes easy to the savage mind to identify the particular spirit, as when the Tasmanian ascribes a gnawing disease to his having unwittingly pronounced the name of a dead man, who thus summoned has crept into his body, and is consuming his liver; or when the sick Zulu believes that some dead ancestor he sees in a dream has caused his ailment, wanting to be propitiated with the sacrifice of an ox; or when the Samoan persuades himself that the ancestral souls, who on occasion reveal themselves by talking through the voices of living members of the family, are the same beings who will take up their abode in the heads or stomachs of living men and cause their illness and death. Here, then, the demon appears in what seems its original character of a human ghost. We may notice in the last example the frequent case of the man's mind being so thoroughly under the belief in a spirit possessing him that he speaks in the person of that spirit, and gives its name; the bearing of this on oracular possession will appear presently. In many, perhaps in most cases, however, the disease-demon is not specially described as a human ghost; for instance, some Malay tribes in their simple theory of diseases are content to say that one kind of demon causes small-pox, another brings on swellings, and so on. The question is whether in such cases the human character has merely dropped away, and this seems likely from the very human fashion in which the demons are communicated with, they are talked to with entreaties or threats, enticed out with offerings of food, or driven away with noises and blows, just as though they were human souls accessible to the same motives as when they were in the body. Thus the savage theory of demoniacal possession has for its natural result the practice of exorcism or banishment of the spirit as the regular means of cure, as where, to select

these from hundreds of instances, the Antilles Indians in Columbus's time went through the pretence of pulling the disease off the patient and blowing it away, bidding it begone to the mountain or the sea or where the Patagonians till lately, believing every sick person to be possessed by an evil demon, drove it away by beating at the bed's head a drum painted with figures of devils.

That such modern savage notions fairly represent the doctrine of disease-possession in the ancient world is proved by the records of the earliest civilized nations. The very charms still exist by which the ancient Egyptians resisted the attacks of the wicked souls who, become demons, entered the bodies of men to torment them with diseases and drive them to furious madness. The doctrine of disease among the ancient Babylonians was that the swarming spirits of the air entered man's body, and it was the exorcist's duty to expel by incantations "the noxious neck-spirit," "the burning spirit of the entrails which devours the man," and to make the piercing pains in the head fly away "like grasshoppers" into the sky. (See *Records of the Past*, vols 1., II., &c; Birch's trans of the Egyptian *Book of the Dead*, see below; Maspero, *Histoire Ancienne des Peuples de l'Orient*, p. 41; Lenormant, *La Magie chez les Chaldéens*, &c.) The transition-stage of the ancient belief in the classical period of Greece and Rome is particularly interesting. The scientific doctrine of medicine was beginning to encroach upon it, but it was still current opinion that a fit was an attack by a demon (*ἐπιληψία* = "seizure," hence English *epilepsy*), that fury or madness was demoniacal possession (*δαίμων* = to be possessed by an evil spirit, hence English *dæmoniac*, &c), that madmen were "larvati," i.e., inhabited by ghosts, &c. No record shows the ancient theory more clearly than the New Testament, from the explicit way in which the symptoms of the various affections are described, culminating in the patient declaring the name of his possessing demon, and answering in his person when addressed. The similarity of the symptoms with those which in barbarous countries are still accounted for in the ancient way may be seen from such statements as the following, by a well-known missionary (Rev. J. L. Wilson, *Western Africa*, p. 217):—"Demoniacal possessions are common, and the feats performed by those who are supposed to be under such influence are certainly not unlike those described in the New Testament. Frantic gestures, convulsions, foaming at the mouth, feats of supernatural strength, furious ravings, bodily lacerations, gnashing of teeth, and other things of a similar character, may be witnessed in most of the cases." Among the early Christians the demoniacs or onergumens (*ἐνεργούμενοι*) formed a special class under the control of a clerical order of exorcists, and a mass of evidence drawn from such writers as Cyril, Tertullian, Chrysostom, and Minutius Felix, shows that the symptoms of those possessed were such as modern physicians would class under hysteria, epilepsy, lunacy, &c (See their works, and refs. in Bingham, *Antiquities of the Christian Church*; Maury, *La Magie et l'Astrologie*, part II. ch 2, &c.) Some theologians, while in deference to advanced medical knowledge they abandon the primitive theory of demons causing such diseases in our own time, place themselves in an embarrassing position by maintaining, on the supposed sanction of Scripture, that the same symptoms were really caused by demoniacal possession in the 1st century. A full statement of the arguments on both sides of this once important controversy will be found in earlier editions of the *Encyclopædia Britannica*, but for our times it seems too like a discussion whether the earth was really flat in the ages when it was believed to be so, but became round since astronomers provided a different explanation of the same phenomena. It is more profitable

every object εἰδωλα (or images) of the object are continually being given off in all directions, these enter the organs of sense, and give rise to sensation. The rest of the theory remarkably anticipates certain famous modern theories of perception (1) by its reduction of all sensation, on the objective side, to touch, and (2) by the distinction which it involves between the qualities of extension and resistance, which are said to be the only qualities that really belong to objects of sense, and the other (or secondary) qualities, which are said to exist only through the action of the organs of sense modifying the εἰδωλα.

Sensation, Democritus appears to have taught, is our only source or faculty of knowledge, indeed his first principles admit the existence of no mental faculty of a nature distinct from sensation. He was classed among the most extreme sceptics of antiquity, and tradition attributes to him such sayings as—"There is nothing true, and if there is, we do not know it," "We know nothing, not even if there is anything to know."

The system of Democritus was altogether anti-theological. He denied that the creation of the world was in any way due to reason. He also rejected all the popular mythology; but, according to one account, he taught that, as men were produced by the motion of the atoms, so was produced a race of grander beings, of similar form, and, though longer-lived, still mortal, who influence human affairs, some benevolently, some malevolently, and who appear to men in dreams.

The moral system of Democritus is strikingly like the negative side of the system of Epicurus. The *summum bonum* is placed in an even tranquillity of mind. Fear, and too strong desire, and all that is likely to bring sorrow or even care, are to be avoided, as, for example, notably marriage, to which Democritus cherished the strongest objections. This habit of mind Democritus is said to have himself so well attained that the merry spirit with which he regarded all that happened earned him the title of "the laughing philosopher." Another version, however, asserts that he received the name on account of the scorn which he poured on human ignorance and weakness.

(See *Records of the Past*, vols i., ii., &c.; Birch's trans of the *Egyptian Book of the Dead*, see below, Maspero, *Histoire Ancienne des Peuples de l'Orient*, p. 41; Lenormant, *La Magie chez les Chaldéens*, &c.) The transition-stage of the ancient belief in the classical period of Greece and Rome is particularly interesting. The scientific doctrine of medicine was beginning to encroach upon it, but it was still current opinion that a fit was an attack by a demon (*ἐπιληψία* = "seizure," hence English *epilepsy*), that fury or madness was demoniacal possession (*δαίμων* = to be possessed by an evil spirit, hence English *dæmoniac*, &c.), that madmen were "larvati," i.e., inhabited by ghosts, &c. No record shows the ancient theory more clearly than the New Testament, from the explicit way in which the symptoms of the various affections are described, culminating in the patient declaring the name of his possessing demon, and answering in his person when addressed. The similarity of the symptoms with those which in barbarous countries are still accounted for in the ancient way may be seen from such statements as the following, by a well-known missionary (Rev. J. L. Wilson, *Western Africa*, p. 217):—"Demoniacal possessions are common, and the feats performed by those who are supposed to be under such influence are certainly not unlike those described in the New Testament. Frantic gestures, convulsions, foaming at the mouth, feats of supernatural strength, furious ravings, bodily lacerations, gnashing of teeth, and other things of a similar character, may be witnessed in most of the cases." Among the early Christians the demoniacs or energumens (*ἐνεργούμενοι*) formed a special class under the control of a clerical order of exorcists, and a mass of evidence drawn from such writers as Cyril, Tertullian, Chrysostom, and Minutius Felix, shows that the symptoms of those possessed were such as modern physicians would class under hysteria, epilepsy, lunacy, &c. (See their works, and refs. in Bingham, *Antiquities of the Christian Church*; Maury, *La Magie et l'Astrologie*, part ii. ch. 2, &c.) Some theologians, while in deference to advanced medical knowledge they abandon the primitive theory of demons causing such diseases in our own time, place themselves in an embarrassing position by maintaining, on the supposed sanction of Scripture, that the same symptoms were really caused by demoniacal possession in the 1st century. A full statement of the arguments on both sides of this once important controversy will be found in earlier editions of the *Encyclopædia Britannica*, but for our times it seems too like a discussion whether the earth was really flat in the ages when it was believed to be so, but became round since astronomers provided a different explanation of the same phenomena. It is more profitable

to notice how gradual the change of opinion has been from the doctrine of demon-possession to the scientific theory of disease, and how largely the older view still survives in the world. Not only in savage districts, but in countries whose native civilization is below the European level, such as India and China, the curious observer may still see the exorcist expel the malignant ghost or demon from the patient afflicted with fever, dizziness, frenzy, or any unaccountable ailment. (See Ward, *History of the Hindoos*, vol. i. p. 155, vol. ii. p. 183; Roberts, *Oriental Illustrations of the Scriptures*, p. 529; Doolittle, *Social Life of the Chinese*.) The unbroken continuance of the belief in mediæval Europe may be gathered from such works as the excellent treatise by Maury, *La Magie et l'Astrologie dans l'Antiquité et au Moyen Age*, already referred to. Even in the 18th century was published with ecclesiastical approval a regular exorcist's manual, the *Fusus et Flagellum Daemonum*, Auctore R. P. F. Hieronimo Mengo (1727), which among its curious contents gives instructions how to get the better of those cunning demons who hide in the bodies of men and vex them with diseases, and which are apt when expelled to take refuge in the patient's hair. The gradual shifting of opinion is marked by the attempt to reconcile the older demonology with the newer medicine. This argument, which appears among the early Christian fathers, is worked out most elaborately in that curious museum of demonology, the *Disquisitiones Magicæ* of Martin Delrio, published as late as 1720. While inveighing against those physicians who maintain that all diseases have natural causes, this learned Jesuit admits that men may be dumb, epileptic, or lunatic without being obsessed; but what the demons do is that, finding the disposition of epileptics suitable, they insinuate themselves into them; also they attack lunatics, especially at full moon, when their brains are full of humours, or they introduce diseases by stirring up the black bile, sending blacks into the brain and cells of the nerves, and setting obstructions in the ears and eyes to cause deafness and blindness. Looking at the date of this celebrated work, we cannot wonder that in benighted districts of Europe the old diabolical possession and its accompanying exorcism may still now and then be met with, as in 1861 at Morzine in Savoy¹ (See A. Coustaing, *Relation sur une Epidémie d'Hystéro-Démonopathie*, Paris, 1863). One of the last notable cases of this kind in England was that of George Lukins of Yatton, a knavish epileptic out of whom seven devils were exorcised by seven clergymen, at the Temple Church at Bristol, on June 13, 1788 (See *Encyc. Brit.* 3d to 6th editions, art. "Possession").

The derivation of the ideas of demons from the phantoms seen in dreams has already been instanced where the apparition is that of a dead man, but there are peculiar kinds of demons which are to be considered specially from this point of view. In savage animism, as among the Australians, what we call a *nightmare* is of course recognized as a demon, and though we have long learnt to interpret it subjectively as arising from some action of the sleeper's brain, it is interesting to remember that its name remains proof of the same idea among our ancestors (Anglo-

Saxon *mæ* = spirit, elf, &c., compare old German *mar* = elf, demon, *nahtmar* = nightmare,—see Grimm, *Deutsche Mythologie*, p. 433.) The *vampires*, or drinkers (Old Russian *upir*), well known in Slavonic regions, are a variety of the nightmare, being witch souls or ghosts who suck the blood of living victims, thus accounting for their becoming pale and bloodless, and falling into decline (See Grohmann, *Aberglauben aus Böhmen*, p. 21; Ralston, *Songs of the Russian People*, p. 410.) From dreams are avowedly formed the notions of *incubi* and *succubi*, those nocturnal demons who consort with women and men in their sleep. From the apparent distinctness of their evidence, these beings are of course well known in savage demonology, and in connection with them there already arises among uncultured races the idea that children may be engendered between spirits and human mothers (See Martin, *Martin's Tonga Islands*, vol. ii. p. 119.) For an ancient example of the general belief in this class of demons, no better could be chosen than that of the early Assyrians, whose name for a succubus, *lilit*, evidently gave rise to the Rabbinical tale of Adam's demon wife *Lilith*. (See Lenormant, *op. cit.* p. 36.) The literature of mediæval sorcery abounds in mentions of this belief, of which the absurd pseudo-philosophical side comes well into view in the chapter of Delrio (*lib. ii. quest. 15*), "*Ausant nunquam demones incubi et succubi, et ex tali congressu proles nasci queat?*" But its serious side is shown by the accusation of consorting with such demons being one of the main charges in the infamous bull of Innocent VIII., which brought judicial torture and death upon so many thousands of wretched so-called witches. (See Roskoff, *Gerichte des Teufels*, vol. ii. p. 222.) It further throws light on demonology that the frightful spectres seen in such affections as delirium tremens have of course been interpreted as real demons. It is needless to give instances from among savage tribes, for the connection between such phantoms and the doctrine of demoniacal possession is shown in its most primitive state in modern Europe. In the *Fusus Daemonum*, p. 12, it is mentioned that demons before entering human bodies are apt to appear in some terrible form or deformity, human or bestial, and while they seem to the patients suddenly to vanish, then they enter into their bodies. By this supposition the disappearance of the phantom and the accompanying illness of the delirious patient are ingeniously accounted for at one stroke.

Though the functions ascribed to demons in savage philosophy are especially connected with disease, they are by no means exclusively so, but the swarming host of spirits pervading the world is called on to account for any events which seem to happen by some unseen but controlling influence. Some cause must lead the wild man to find game one day and come back empty another, to stumble and hurt himself in the dusk, to lose his way and become bewildered in the dark forest, where the cries of animals and other sounds seem to him spirit-voices misleading or mocking him. For all such events requiring explanation savages find personal causes in intervening demons, who are sometimes ghosts, as when an American Indian falling into the fire will say that an angry ancestral spirit pushed him in; or they may be simply spirits of undefined origin, like those whom the Australians regard as lurking everywhere, ready to do harm to the poor black-fellow. To compare this state of thought with that of the classic world, we have but to remember the remark of Hippocrates about the superstitious who believed themselves infested day and night by malicious demons, or the Romans' fear of those harmful ghost-demons the *lemures*, whom they got rid of by the quaint ceremonies of the annual *Lemuralia*. How permanent these demon-ideas

¹ The *Times*, in November 1876, contains an account in the casting out of devils by a priest in the Church of the Holy Spirit in Barcelona, during the preceding month. On one occasion the patient, a young woman of seventeen or eighteen, lay on the floor before the altar, writhing in convulsions with distorted features and foaming at the mouth, while the priest carried on a dialogue with the devil, whom he addressed by the name of Rasbel, the fiend's answers being of course spoken by the voice of the frantic girl herself. At last a number of demons were supposed to come out of the patient's body, and such scenes were repeated for days in the presence of many spectators till a riot arose, and the civil authorities intervening put a stop to the whole affair.

have been from the infaney of culture, may be well shown by the permanence of the practice of holding at intervals such special ceremonies to expel them. In Siam the people first hunt the demons out of the houses, and then drive them with cannon-shots through the streets till they get them outside the walls into the forest. In Old Calabar they put puppets along the streets leading to the sea, to entice the demons into, and then at dead of night a sudden rush is made by the negroes with whips and torches to drive the spirits down into the sea. Not only do other barbaric regions, such as the South Sea Islands and Peru, furnish similar examples of the expulsion of demons, but it may still be seen among European peasantry. In Sweden, Easter-tide is the season for a general purging of the land from the evil spirits and trolls of the old heathendom; and in many parts of Germany unseen witches are to this day driven out on Walpurgs-night with crack of whip and blast of horn. (See a collection of cases in Bastian and Hartmann, *Zeitschrift für Ethnologie*, 1869, p. 189; also Hylten-Cavallius, *Wärend och Wärdarne*, part i. p. 178) In these cases it is generally unfavourable influences which are considered as due to the demons. But favourable events are even by savages often recognized as due to the intervention of some kindly spirit, and especially to a guardian or patron demon, whose help accounts for what among ourselves is often not much more rationally considered to be "luck." It is often a recognized ancestral soul which from natural affection undertakes this duty, as when a Tasmanian has been known to account for escape from danger by the idea that his father's soul was still watching over him. But it need not be so; and among the American Indians or West Africans, where each man lives in constant imaginary intercourse with his patron-spirit, talking with it, making it offerings, and trusting to its guidance in difficulty and protection from danger, this spirit may be revealed in a dream or vision, and is often connected with some object known as a "medicine" or "fetish," but is seldom identified with any particular ghost. In Greek literature this idea is best exemplified by the lines of Menander on the good demon whom every man has from birth as his guide through the mysteries of life (ap. Clem. Alex., *Stromat.* v.); the most popularly known example is the so-called "demon" of Socrates, but he himself did not give such personal definiteness to the divine or dæmonic influence (δαμόνιον) which warned him by what he described as a voice or sign (see Zeller, *Socrates*, ch. 4). The primitive idea of the patron spirit is carried on in the Roman *genius*, whose name (even without the addition of "natalis") indicates that it is born with the person whom it accompanies through life. Its place very closely corresponds to that occupied in modern folklore by the guardian angel. There are districts in France where a peasant meeting another, salutes not only the man, but his "companion," the guardian angel who is supposed to be invisibly at his side.

Among attendaut and patron demons, as recognized in the general belief of mankind, a specially important class is formed by the familiar spirits who accompany sorcerers, giving them mysterious knowledge, uttering oracular responses through their voices, enabling them to perform wonderful feats, bringing them treasure or injuring their enemies, and doing other spiritual services for them. From the descriptions of sorcerers among the lower nations, it is at once evident that their supposed intercourse with demons is closely connected with the symptoms of disease-possession. Thus among the Zulus, "the disease which precedes the power to divine" is distinctly hysterical, the patient's morbid sensitiveness and intensely vivid imagination of sights and voices fitting well with his persuasion that he is under the control of some ancestral ghost. So

well is this connection recognized among races like the Patagouians and rude tribes of Siberia, that children with an hereditary tendency to epilepsy are brought up to the profession of magicians. Where the sorcerer has not naturally such symptoms of possession by a controlling demon, he is apt to bring them on by violent dancing and beating drums, or by drugs, or to simulate them by mere knavery; which latter is really the most convincing proof that the original notion of the demon of the magician did not arise from imposture, but from actual belief that the morbid excitement, hallucination, and raving consequent on mental disease were caused by spirits other than the man's own soul, in possession of his body. The primitive and savage theory of inspiration by another spirit getting inside the body is most materialistic, and cheating sorcerers accordingly use *ventriloquism* of the original kind, which (as its name implies) is supposed to be caused by the voice of a demon inside the body of the speaker, who really himself talks in a feigned human voice, or in squeaking or whistling tones thought suitable to the thin-bodied spirit-visitor. The familiar spirit may be a human ghost or some other demon, and may either be supposed to enter the man's body or only to come into his presence, which is somewhat the same difference as whether in disease the demon "possesses" or "obsesses" a patient, i.e., controls him from inside or outside. Thus the Greenland *angelok*, or sorcerer, is described as following his profession by the aid of a *toingak*, or familiar spirit (who may be an ancestral ghost), whom he summons by drumming, and with whom he is heard by the bystanders to carry on a conversation within the hut, obtaining information which enables him to advise as to the treatment of the sick, the prospect of good or bad weather, and the other topics of the business of a soothsayer. Passing over the intermediate space which divides the condition of savages from that of mediæval or modern Europeans, we shall find, so far as the doctrine of familiar demons has survived, that it has changed but little in principle. In the witch trials a favourite accusation was that of having a familiar demon. Sir Walter Scott's *Demonology and Witchcraft* contains among others the case of Bessie Dunlop, whose familiar was the ghost of one Thome Reid, killed at the battle of Pinkie (1547), who enabled her to give answers to such as consulted her about the ailments of human beings or cattle, or the recovery of things lost or stolen. This miserable woman, chiefly on her own confession, was as usual "convinced and burnt." Here the imagined demon was a human soul; but other spirits thus attended sorcerers and diviners, such as the spirit called Hudhart, who enabled a certain Highland woman to prophesy as to the conspiracy to murder James I. of Scotland. Dissertations on the art of raising demons for the sorcerers' service, and even the actual charms and ceremonies to be used, form a large part of the precepts of magical books. (See Ennemoser, *History of Magic*; Horst, *Zauberbibliothek*, and other works already cited.) Among the latest English books treating seriously of this "black art" is Sibly's *Illustration of the Occult Sciences*, of which a 10th edition, in 4to, bears date London, 1807. The statute of James I. of England enacts that all persons invoking any evil spirit, or consulting, covenanting with, entertaining, employing, feeding, or rewarding any evil spirit, should be guilty of felony, and suffer death. This was not repealed till the reign of George II. Educated public opinion has now risen above this level; but popular credulity is still to be worked upon by much the same means as those employed by savage sorcerers professing intercourse with familiar spirits. At "spiritualistic séances" the convulsive and hysterical symptoms (pretended or real) of the "medium" under the "control" of his "guiding spirit" are much the same as those which

teen years had learned Latin, Greek, and some Hebrew, in addition to acquiring much general knowledge. At the age of sixteen years and a half he entered Trinity College, Cambridge, and studied mathematics, partly under the tuition of Airy, subsequently the astronomer royal. In 1825 he gained a Trinity scholarship. De Morgan's attention was by no means confined to mathematics, and his love of wide reading somewhat interfered with his success in the mathematical tripos, in which he took the fourth place in 1827, before he had completed his twenty-first year. He was prevented from taking his M.A. degree, or from obtaining a fellowship, to which he would doubtless have been elected, by his conscientious objection to signing the theological tests then required from masters of arts and fellows at Cambridge. A strong repugnance to any sectarian restraints upon the freedom of opinion was one of De Morgan's most marked characteristics throughout life.

A career in his own university being closed against him, he entered Lincoln's Inn; but had hardly done so when the establishment, in 1828, of the university of London, in Gower Street, afterwards known as University College, gave him an opportunity of continuing his mathematical pursuits. At the early age of twenty-two years he gave his first lecture as professor of mathematics in a college which he served with the utmost zeal and success for a third of a century. His connection with the college, indeed, was interrupted in 1831, when a disagreement with the governing body caused De Morgan and some other professors to resign their chairs simultaneously. When, in 1836, his successor Mr White was accidentally drowned, De Morgan was requested to resume the professorship. It may be added that his choice of a literary and scientific career was made against the advice of his relatives and friends, who, on his entering Lincoln's Inn, confidently anticipated for him a distinguished and lucrative career at the bar.

In 1837 De Morgan married Sophia Elizabeth, daughter of William Freud, a Unitarian in faith, a mathematician and actuary in occupation, a notice of whose life, written by his son-in-law, will be found in the *Monthly Notices of the Royal Astronomical Society* (vol. v). Henceforward De Morgan's life is scarcely more than a record of his constant labours, and his innumerable publications. As in the case of many scholars, the even tenor of his life was unbroken by remarkable incidents. Surrounded by a growing family, ultimately seven in number, he sought happiness in his home, in his library, and in the energetic and vigorous discharge of his college duties. He seldom travelled or enjoyed relaxation, and could with difficulty be induced to remain many days from home.

As a teacher of mathematics De Morgan was unrivalled. He gave instruction in the form of continuous lectures delivered *extempore* from brief notes. The most prolonged mathematical reasoning, and the most intricate formulae, were given with almost infallible accuracy from the resources of his extraordinary memory. De Morgan's writings, however excellent, give little idea of the perspicuity and elegance of his *viva voce* expositions, which never failed to fix the attention of all who were worthy of hearing him. Many of his pupils have distinguished themselves, and, through Mr Todhunter and Mr Routh, he has had an important influence on the modern Cambridge school. In addition to occasional extra courses, it was his habit to give two lectures on each of the six week days throughout the working session of thirty weeks or more. Each lecture was exactly one hour and a quarter in length, and at the close a number of questions and problems were always given, to which the pupils returned written answers. These were all corrected by the professor's own hand, and personal explanations given before or after the lecture.

Although the best hours of the day were thus given to arduous college work, his public labours in other directions were extensive. For thirty years he took an active part in the business of the Royal Astronomical Society, editing its publications, supplying obituary notices of members, and for 18 years acting as one of the honorary secretaries. His work for this society alone, it is said, would have been occupation enough for an ordinary man. He was also frequently employed as consulting actuary, a business in which his mathematical powers, combined with sound judgment and business-like habits, fitted him to take the highest place.

De Morgan's mathematical writings contributed powerfully towards the progress of the science. His memoirs on the "Foundation of Algebra," in the 7th and 8th volumes of the *Cambridge Philosophical Transactions*, contain some of the most important contributions which have been made to the philosophy of mathematical method; and Sir W. Rowan Hamilton, in the preface to his *Lectures on Quaternions*, refers more than once to those papers as having led and encouraged him in the working out of the new system of quaternions. The work on *Trigonometry and Double Algebra*, published by De Morgan in 1849, contains in the latter part a most luminous and philosophical view of existing and possible systems of symbolic calculus. But De Morgan's influence on mathematical science in England can only be estimated by a review of his long series of publications, which commence, in 1828, with a translation of part of Bourdon's *Elements of Algebra*, prepared for his students. In 1830 appeared the first edition of his well-known *Elements of Arithmetic*, which has been widely used in schools, and has done much to raise the character of elementary training. It is distinguished by a simple yet thoroughly philosophical treatment of the ideas of number and magnitude, as well as by the introduction of new abbreviated processes of computation, to which De Morgan always attributed much practical importance. Second and third editions were called for in 1832 and 1835, and more than 20,000 copies have been sold; the book is still in use, a sixth edition having been issued in 1876.

De Morgan's other principal mathematical works were *The Elements of Algebra*, 1835, a valuable but somewhat dry elementary treatise; the *Essay on Probabilities*, 1838, forming the 107th volume of *Lardner's Cyclopædia*, still much used, being probably the best simple introduction to the theory in the English language; and *The Elements of Trigonometry and Trigonometrical Analysis, preliminary to the Differential Calculus*, 1837.

Several of his mathematical works were published by the Society for the Diffusion of Useful Knowledge, of which De Morgan was at one time an active member. Among these may be mentioned the great *Treatise on the Differential and Integral Calculus*, 1842, which still remains the most extensive and complete English treatise on the subject; the *Elementary Illustrations of the Differential and Integral Calculus*, first published in 1832, but often bound up with the larger treatise; the valuable essay, *On the Study and Difficulties of Mathematics*, 1831; and a brief treatise on *Spherical Trigonometry*, 1834. By some accident the work on probability in the same series, written by Lubbock and Drinkwater-Bothune was attributed to De Morgan, an error which seriously annoyed his nice sense of bibliographical accuracy. For fifteen years he did all in his power to correct the mistake, and finally wrote to the *Times* to disclaim the authorship. (See *Monthly Notices* of the Royal Astronomical Society, vol. xxvi p. 118.)

Two of his most elaborate treatises are to be found in the *Encyclopædia Metropolitana*, namely the articles on the

Calculus of Functions, and the Theory of Probabilities. The former article contains a profound investigation into the principles of symbolic reasoning; the latter is still the most complete mathematical treatise on the subject in the English language, giving as it does a resumé of Laplace's *Théorie Analytique des Probabilités*. De Morgan's minor mathematical writings are scattered over various periodicals, five papers will be found in the *Cambridge Mathematical Journal*, ten in the *Cambridge and Dublin Mathematical Journal*, several in the *Philosophical Magazine*, while others of more importance are printed in the *Cambridge Philosophical Transactions*. A list of these and other papers will be found in the *Royal Society's Catalogue*, which contains 42 entries under the name of De Morgan.

In spite of the excellence and extent of his mathematical writings, it is probably as a logical reformer that De Morgan will be best known to future times. In this respect he stands alongside of his great contemporaries Hamilton and Boole, as one of several independent discoverers of the all-important principle of the quantification of the predicate. Unlike most mathematicians, De Morgan always laid much stress upon the importance of logical training. In his admirable papers upon the modes of teaching arithmetic and geometry, originally published in the *Quarterly Journal of Education* (reprinted in *The Schoolmaster*, vol. n.), he remonstrated against the neglect of logical doctrine. In 1839 he produced a small work called *First Notions of Logic*, giving what he had found by experience to be much wanted by students commencing with *Euclid*.

In October 1846 he completed the first of his original investigations, in the form of a paper printed in the *Transactions of the Cambridge Philosophical Society* (vol. viii No. 29). In this paper the principle of the quantified predicate was referred to, and there immediately ensued a memorable controversy with Sir W. Hamilton regarding the independence of De Morgan's discovery, some communications having passed between them in the autumn of 1846. The details of this dispute will be found by those interested in the original pamphlets, in the *Athenæum* newspaper, or in the appendix to De Morgan's *Formal Logic*. Suffice it to say that the independence of De Morgan's discovery was subsequently recognized by Hamilton, and that those acquainted with De Morgan's character could never suppose that it was otherwise. Moreover, the eight forms of proposition adopted by De Morgan as the basis of his system partially differ from those which Hamilton derived from the quantified predicate. The general character of De Morgan's development of logical forms was wholly peculiar and original on his part.

Not a year passed before De Morgan, late in 1847, published his principal logical treatise, called *Formal Logic, or the Calculus of Inference, Necessary and Probable*. This contains a reprint of the *First Notions*, an elaborate development of his doctrine of the syllogism, and of the numerically definite syllogism, together with chapters of great interest on probability, induction, old logical terms, and fallacies. The severity of the treatise is relieved by characteristic touches of humour, and by quaint anecdotes and allusions furnished from his wide reading and perfect memory.

There followed at intervals, in the years 1850, 1858, 1860, and 1863, a series of four elaborate memoirs on the "Syllogism," printed in volumes ix. and x. of the *Cambridge Philosophical Transactions*. These papers taken together constitute a great treatise on logic, in which he substituted improved systems of notation, and developed a new logic of relations, and a new onymatic system of logical expression. Apart, however, from their principal purpose,

these memoirs are replete with acute remarks, happy illustrations, and abundant proofs of De Morgan's varied learning. Unfortunately these memoirs are accessible to few readers, otherwise they would form invaluable reading for the logical student. In 1860 De Morgan endeavoured to render their contents better known by publishing a *Syllabus of a Proposed System of Logic*, from which may be obtained a good idea of his symbolic system, but the more readable and interesting discussions contained in the memoirs are of necessity omitted. The article "Logic" in the *English Cyclopædia* (1860) completes the list of his logical publications.

Throughout his logical writings De Morgan was led by the idea that the followers of the two great branches of exact science, logic and mathematics, had made blunders,—the logicians in neglecting mathematics, and the mathematicians in neglecting logic. He endeavoured to reconcile them, and in the attempt showed how many errors an acute mathematician could detect in logical writings, and how large a field there was for discovery. But it may be doubted whether De Morgan's own system, "horrent with mysterious symbols," as Hamilton aptly described it, is fitted to exhibit the real analogy between quantitative and qualitative reasoning, which is rather to be sought in the logical works of Boole. (See BOOLE, vol. iv. p. 47.)

Perhaps the largest part, in volume, of De Morgan's writings remains still to be briefly mentioned, it consists of detached articles contributed to various periodical or composite works. During the years 1833-43, he contributed very largely to the first edition of the *Penny Cyclopædia*, writing chiefly on mathematics, astronomy, physics, and biography. His articles of various length cannot be less in number than 850, as may be ascertained from a signed copy in the British Museum, and they have been estimated to constitute a sixth part of the whole *Cyclopædia*, of which they formed perhaps the most valuable portion. He also wrote biographies of Newton and Halley for Knight's *British Worthies*, various notices of scientific men for the *Gallery of Portraits*, and for the uncompleted *Biographical Dictionary of the Useful Knowledge Society*, and at least seven articles in Smith's *Dictionary of Greek and Roman Biography*.

Some of De Morgan's most interesting and useful minor writings are to be found in the *Companions to the British Almanack*, to which he contributed without fail one article each year from 1831 up to 1857 inclusive. In these carefully written papers he treats a great variety of topics relating to astronomy, chronology, decimal coinage, life-assurance, bibliography, and the history of science. Most of them are as valuable now as when written.

Among De Morgan's miscellaneous writings may be mentioned his *Explanation of the Gnomonic Projection of the Sphere*, 1836, including a description of the maps of the stars, published by the Useful Knowledge Society; his *Treatise on the Globes, Celestial and Terrestrial*, 1845; and his remarkable *Book of Almanacks*, (second edition 1871), which contains a series of 25 almanacks, so arranged with indices of reference, that the almanack for any year, whether in old style or new, from any epoch, ancient or modern, up to 2000 A.D., may be found without difficulty, means being added for verifying the almanack and also for discovering the days of new and full moon from 2000 B.C. up to 2000 A.D. De Morgan expressly draws attention to the fact that the plan of this book was that of Francœur and Ferguson, but the plan was developed by one who was an unrivalled master of all the intricacies of chronology. The two best tables of logarithms, the small five-figure tables of the Useful Knowledge Society (1839 and 1857), and Shroen's Seven Figure-Table (5th ed. 1855), were printed under De Morgan's superintendence. Several works edited by him will be found mentioned in the *British Museum Catalogue*. His numerous anonymous contributions through a long series of years to the *Athenæum*, and to *Notes and Queries*, and his occasional articles in the *North British Review*, *Macmillan's Magazine*, &c., must be passed over with this bare mention.

Considerable labour was spent by De Morgan upon the subject of decimal money. He was a great advocate of the pound and mil scheme. His evidence on this subject was sought by the Royal Commission, and, besides constantly supporting the Decimal Association in periodical publications, he published several separate pamphlets on the subject.

One marked character of De Morgan was his intense and yet reasonable love of books. He was a true bibliophile, and loved to surround himself, as far as his means allowed, with curious and rare books. He revelled in all the mysteries of watermarks, title pages, colophons, catch-words, and the like; yet he treated biblio-

graphy as an important science. As he himself wrote, "the most worthless book of a bygone day is a record worthy of preservation; like a telescopic star, its obscurity may render it unavailable for most purposes, but it serves, in hands which know how to use it, to determine the places of more important bodies." His evidence before the Royal Commission on the British Museum in 1850, (Questions 5704*–5815,* 6481–6513, and 8966–8967), should be studied by all who would comprehend the principles of bibliography, or the art of constructing a catalogue, his views on the latter subject corresponding with those carried out by Panizzi in the *British Museum Catalogue*. A sample of De Morgan's bibliographical learning is to be found in his account of *Arithmetical Books, from the Invention of Printing* (1847), and finally in his *Budget of Paradoxes*. This latter work consists of articles most of which were originally published in the *Athenæum*, describing the various attempts which have been made to invent a perpetual motion, to square the circle, or to trisect the angle; but De Morgan took the opportunity to include many curious bits gathered from his extensive reading, so that the *Budget* as reprinted by his widow (1872), with much additional matter prepared by himself, forms a remarkable collection of scientific and De Morgan's correspondence with contemporary scientific men was very extensive and full of interest. It remains unpublished, as does also a large mass of mathematical tracts which he prepared for the use of his students, treating all parts of mathematical science, and embodying some of the matter of his lectures. De Morgan's library was purchased by Lord Overstone, and presented to the university of London.

From the above enumeration it will be apparent that the extent of De Morgan's literary and scientific labours was altogether extraordinary; nor was quality sacrificed to quantity. On the contrary every publication was finished with extreme care and accuracy, and no writer can be more safely trusted in every thing which he wrote. It is possible that his continual efforts to attain completeness and absolute correctness injured his literary style, which is wanting in grace; but the estimation in which his books are held is shown by the fact that they are steadily rising in market price. Apart from his conspicuous position as a logical and mathematical discoverer, we may conclude that hardly any man of science in recent times has had a more extensive, though it may often be an unfelt influence, upon the progress of exact and sound knowledge.¹

De Morgan has left no published indications of his opinions on religious questions, in regard to which he was extremely reticent. He seldom or never entered a place of worship, and declared that he could not listen to a sermon, a circumstance perhaps due to the extremely strict religious discipline under which he was brought up. Nevertheless there is reason to believe that he was of a deeply religious disposition. Like Faraday and Newton he entertained a confident belief in Providence, founded not on any tenuous method of inference, but on personal feeling. His hope of a future life also was vivid to the last.

In the year 1866 a life as yet comparatively free from trouble became clouded by the circumstances which led him to abandon the institution so long the scene of his labours. The refusal of the council to accept the recommendation of the senate, that they should appoint an eminent Unitarian minister to the professorship of logic and mental philosophy, revived all De Morgan's sensitiveness on the subject of sectarian freedom; and, though his feelings were doubtless excessive, there is no doubt that gloom was thrown over his life, intensified in 1867 by the loss of his son George Campbell De Morgan, a young man of the highest scientific promise, whose name, as De Morgan expressly wished, will long be connected with the London Mathematical Society, of which he was one of the founders. From this time De Morgan rapidly fell into ill-health, previously almost

unknown to him, dying on the 18th March 1871. An interesting and truthful sketch of his life will be found in the *Monthly Notices of the Royal Astronomical Society*, for the 9th February 1872, vol. xxii. p. 112, written by Mr Ranyard, who says, "He was the kindest, as well as the most learned of men—benignant to every one who approached him, never forgetting the claims which weakness has on strength" (W. S. J.)

DEMOSTHENES was born in 384 B.C. His father, who bore the same name, was an Athenian citizen belonging to the deme of Pæania. His mother, Cleobule, was the daughter of Gylon, a citizen who had been active in procuring the protection of the kings of Bosphorus for the Athenian colony of Nymphæon in the Crimea, and whose wife was a native of that region. On these grounds the adversaries of Demosthenes, in after-days, used absurdly to taunt him with a traitorous or barbarian ancestry. The boy had a bitter foretaste of life. He was seven years old when his father died, leaving property (in a manufactory of swords, and another of upholstery) worth about £3500, which, invested as it seems to have been (20 per cent. was not thought exorbitant), would have yielded rather more than £600 a year. £300 a year was a very comfortable income at Athens, and it was possible to live decently on a tenth of it. Nicias, a very rich man, had property equivalent, probably, to not more than £4000 a year. Demosthenes was born, then, to a handsome, though not a great fortune. But his guardians—two nephews of his father, Aphobus and Demophon, and one Therippides—abused their trust, and handed over to Demosthenes, when he came of age, rather less than one-seventh of his patrimony, perhaps between £50 and £60 a year. Demosthenes, after studying with Isæus—then the great master of forensic eloquence and of Attic law, especially in will cases²—brought an action against Aphobus, and gained a verdict for about £2400. But it does not appear that he got the money, and, after some more fruitless proceedings against Onetor, the brother-in-law of Aphobus, the matter was dropped,—not, however, before his relatives had managed to throw a public burden (the equipment of a ship of war) on their late ward, whereby his resources were yet further straitened. He now became a professional writer of speeches or pleas for the law-courts, sometimes speaking himself. Biographers have delighted to relate how painfully Demosthenes made himself a tolerable speaker,—how, with pebbles in his mouth, he tried his lungs against the waves, how he declaimed as he ran up hill, how he shut himself up in a cell, having first guarded himself against a longing for the haunts of men by shaving one side of his head, how he wrote out Thucydides eight times, how he was derided by the Assembly and encouraged by a judicious actor who met him moping about the Peiræus. He certainly seems to have been the reverse of athletic (the stalwart Æschines upbraids him with never having been a sportsman), and he probably had some sort of defect or impediment in his speech as a boy. Perhaps the most interesting fact about his work for the law-courts is that he seems to have continued it, in some measure, through the most exciting parts of his great political career. The speech for Phormio belongs to the same year as the plea for Megalopolis. The speech for Boeotus "Concerning the Name" comes between the First Philippic and the First Olynthiac. The speech against Pantænetus comes between the speech "On the Peace" and the Second Philippic.

¹ In a notice of De Morgan's character it is impossible to omit a reference to his witty sayings, some specimens of which are preserved in Dr Sadler's most interesting *Diary of Henry Crabb Robinson* (1869), which also contains a humorous account of H. C. R. by De Morgan. It may be added that De Morgan was a great reader and admirer of Dickens; he was also fond of music, and a fair performer on the flute.

² In Jebb's *Attic Orators from Antiphon to Isæus*, vol. ii. p. 267 f., the traditions of the relation between Demosthenes and Isæus are examined in detail. It is there shown that the intercourse of the men can scarcely have been either intimate or prolonged, but that Demosthenes undoubtedly learned from Isæus the art of grappling with a forensic adversary in close and strenuous argument.

Political
career—
its unity.

The political career of Demosthenes, from his first direct contact with public affairs in 355 B.C. to his death in 322, has no essential unity. It is the assertion, in successive forms adapted to successive moments, of unchanging principles. Externally, it is divided into the chapter which precedes and the chapter which follows Chæroneia. But its inner meaning, the secret of its indomitable vigour, the law which harmonizes its apparent contrasts, cannot be understood unless it is regarded as a whole. Still less can it be appreciated in all its large wisdom and sustained self-mastery if it is viewed merely as a duel between the ablest champion and the craftiest enemy of Greek freedom. The time indeed came when Demosthenes and Philip stood face to face as representative antagonists in a mortal conflict. But, for Demosthenes, the special peril represented by Philip, the peril of subjugation to Macedon, was merely a disastrous accident. Philip happened to become the most prominent and most formidable type of a danger which was already threatening Greece before his baleful star rose. As Demosthenes said to the Athenians, if the Macedonian had not existed, they would have made another Philip for themselves. Until Athens recovered something of its old spirit, there must ever be a great standing danger, not for Athens only, but for Greece,—the danger that sooner or later, in some shape, from some quarter—no man could foretell the hour, the manner, or the source—barbarian violence would break up the gracious and undefiled tradition of separate Hellenic life.

e rela-
tion of
Athens to
Greece.

What is the true relation of Athens to Greece? The answer which he gave to this question is the key to the life of Demosthenes. Athens, so Demosthenes held, is the natural head of Greece. Not, however, as an empress holding subject or subordinate cities in a dependence more or less compulsory. Rather as that city which most nobly expresses the noblest attributes of Greek political existence, and which, by her pre-eminent gifts both of intellect and of moral insight, is primarily responsible, everywhere and always, for the maintenance of those attributes in their integrity. Wherever the cry of the oppressed goes up from Greek against Greek, it is the voice of Athens which should first remind the oppressor that Hellene differs from barbarian in postponing the use of force to the persuasions of equal law. Wherever a barbarian hand offers wrong to any city of the Hellenic sisterhood, it is the arm of Athens which should first be stretched forth in the holy strength of Apollo the Averter. Wherever among her own children the ancient loyalty is yielding to love of pleasure or of base gain, there, above all, it is the duty of Athens to see that the central hearth of Hellas is kept pure. Athens must never again seek "empire" in the sense which became odious under the influence of Cleon and Hyperbolus,—when, to use the image of Aristophanes, the slaves were as Babylonian slaves grinding in the Athenian mill. Athens must never permit, if she can help it, the re-establishment of such a domination as Sparta exercised in Greece from the battle of Egospotami to the battle of Leuctra. Athens must aim at leading a free confederacy, of which the members shall be bound to her by their own truest interests. Athens must seek to deserve the confidence of all Greeks alike.

decay of
public
spirit.

Such, in the belief of Demosthenes, was the part which Athens must perform if Greece was to be safe. But reforms must be effected before Athens could be enabled of such a part. The evils to be cured were different phases of one malady. Athens had long been suffering from the profound decay of public spirit. It was of the essence of a Greek commonwealth that the citizen, while perfectly free in his social life, should constantly set his duty to the city above private interests. If the state needs his service in war, he must not hire an inferior substitute to do the work.

If the state requires funds, he must not grudge the money which in quiet times might have been spent on the theatre or the banquet. He must ever remember that, in the phrase of Sophocles, the state is the ship that bears us safe. It does not profit the passenger that his cabin is comfortable if the ship is going down.

Since the early years of the Peloponnesian war, the separation of Athenian society from the state had been growing more and more marked. The old type of the eminent citizen, who was at once statesman and general, had become almost extinct. Politics were now managed by a small circle of politicians. Wars were conducted by professional soldiers whose troops were chiefly mercenaries, and who were usually regarded by the politicians either as instruments or as enemies. The mass of the citizens took no active interest in public affairs. But, though indifferent to principles, they had quickly sensitive partialities for men, and it was necessary to keep them in good humour. Pericles had introduced the practice of giving a small bounty from the Treasury to the poorer citizens, for the purpose of enabling them to attend the theatre at the great festivals,—in other words, for the purpose of bringing them under the concentrated influence of the best Attic culture. A provision eminently wise for the age of Pericles easily became a mischief when the once honourable name of "demagogue" began to mean a flatterer of the mob. Before the end of the Peloponnesian War the festival-money ("theoricon") was abolished. A few years after the restoration of the democracy it was again introduced. But until 354 B.C. it had never been more than a gratuity, of which the payment depended on the Treasury having a surplus. It had never been treated as an annual charge on the revenue, or guaranteed to the citizens as a dividend which they could claim by constitutional right. In 354 B.C. Eubulus became steward of the Treasury. He was an able man, with a special talent for finance, free from all taint of personal corruption, and sincerely solicitous for the honour of Athens, but enslaved to popularity, and without principles of policy. He sought to manage the citizens by humouring to the top of its bent their disinclination for personal sacrifice, and their preference for public show to public strength. More than any other one man, Eubulus represents that new, easy-going, improvident Athens in which the vigilant civic spirit was dead. His first measure was to make the festival-money a permanent item in the budget. Thenceforth this bounty was in reality very much what Demades afterwards called it,—the cement (κόλλα) of the democracy.

Years before the danger from Macedon was urgent, Demosthenes had begun the work of his life,—the effort to lift the spirit of Athens, to revive the old civic loyalty, to rouse the city into taking that place and performing that part which her own welfare as well as the safety of Greece prescribed. His formally political speeches must never be considered apart from his forensic speeches in public causes. The Athenian procedure against the proposer of an unconstitutional law—i.e., of a law incompatible with existing laws—had a direct tendency to make the law-court, in such cases, a political arena. The same tendency was indirectly exerted by the tolerance of Athenian juries (in the absence of a presiding expert like a judge) for irrelevant matter, since it was usually easy for a speaker to make capital out of the adversary's political antecedents. But the forensic speeches of Demosthenes for public causes are not only political in this general sense. They are documents, as indispensable as the Olynthiæ or Philippicæ, for his own political career. Only by taking them along with the formally political speeches, and regarding the whole as one unbroken series, can we see clearly the full scope of the task which he set before him,—a task in which his long

resistance to Philip was only the most dramatic incident, and in which his real achievement is not to be measured by the event of Chæronea.

A famous speech composed for a public crisis opens the political career of Demosthenes with a protest against a signal abuse. In 355 B.C. at the age of twenty-two he wrote the speech "Against Leptines." This contains on legal grounds a proposal that the existing Senate should receive the honor of a public crown. In its larger aspect, it is a denunciation of the corrupt system which the Senate represented, and especially of the manner in which the Treasury had been administered by Aristarchus. In 354 B.C. Demosthenes composed and spoke the oration "Against Leptines," who had effected a similar saving for the state by the expedient of reviving those hereditary exemptions from taxation which had at various times been confirmed in recognition of distinguished merit. The character of Demosthenes and Aristarchus alone had been exempted from the operation of the law. This was the first time that the title of Demosthenes himself had been heard on the public business of Athens, and the occasion was a worthy tribute to the career of a statesman. He answers the objections of the opposition by pointing out that the public interest will not ultimately be served by a wholesale revivification of the public debt. In the same year he delivered his first extempore political speech. The Athenians, induced by the success which Aristarchus had lately given at the court of their allies, and excited by rumors of the hostile preparations, were debating eight days a war with Persia. Demosthenes urges that such an enterprise would be madness; that it would stir up the Greeks; that the energies of the city should be reserved for a real emergency; that that before the city can successfully cope with any war there must be a better organization of resources, and that of all a reform of the navy. The scheme of naval reform which he proposes has characteristic earnestness of detail. We see not clearly he has thought out the question. The same practical and business precision is a striking mark in every speech of Demosthenes which recommends a course of action.

Two years later he is found dealing with a more definite question of foreign policy. Sparta, diverted by the depression of Thebes in the Peloponnesian war, was threatening Megalopolis. Both Sparta and Megalopolis sent embassies to Athens. Demosthenes supported Megalopolis. The aim of Megalopolis would mean the capture of the town of Spartan dominion in the Peloponnese. Athens must maintain the security of any one city. They must reserve the rights of all the Greeks, and since justice may be based on mutual conflicts. In the same year Demosthenes wrote the speech "Against Timarchus," to be spoken by the same Philon who had before presented Aristarchus, and who now conducted an attempt to secure Aristarchus and others from the penalties of embællismenon. The speech "Against Aristarchus," also of 355 B.C. requires that foreign policy should be based on the principle which was now popular in Athens. The Athenian nature of the Thracian Chersonese purely depended for its security on the goodwill of the Thracian prince Cersobleptes. Cersobleptes, a soldier of fortune who had lately placed Athens there, was not the benefactor and the friend of Cersobleptes. Aristarchus proposed that the person of Cersobleptes should be treated with a special suzerainty, by the enactment that whoever attacked his life should be an enemy from all cities of Athens. Demosthenes points out that such a suzerainty is as futile as it is foolish. Athens can secure the continuance of her foreign possessions only in one way—by being strong enough to hold them.

Thus between 355 and 352 Demosthenes had laid down the main lines of his policy. Demosthenes himself

must be guided. Success must be made to feel that they are responsible to the state. They must not be allowed to anticipate judgment on their deserts by voting each other quiet crimes. They must not think to secure misappropriation of public money by giving pensions to pass new laws about embællismenon. Foreign policy must be guided by a larger and more provident conception of Athenian interests. When public embællismenon demands a foreign war, Athens must not rush into it without asking whether it is necessary, whether it will have Greek sympathy, and whether she herself is ready for it. When a strong Greek city threatens a weak one and seeks to purchase Athenian assistance with the title of a benefactor, Athens must remember that duty and justice alike command her to respect the independence of all Greeks. When it is proposed, by way of insurance, to Athenian possessions abroad to dinner the income of a fortified city, Athens must remember that such devices will not only a power which has no army except on paper, and no ships fit to leave their moorings.

On the same day given by when Aristarchus would have enjoyed leave for domestic reform. A larger calling for reform existed, but it was very near. For six years Athens had been at war with Philip on account of the seizure of Amphipolis. Meanwhile he had destroyed Potidæa and founded Philippi. On the Thracian coast he had become master of Abdera and Maronea. On the Thracian coast he had acquired Medea. In a second invasion of Thessaly he had overthrown the Phocians under Onomarchus, and had advanced to Thermopylae, and had the gates of Greece closed against him by an Athenian force. He had then marched to Heraclea on the Euboean, and had obtained a peace in Cardia. He had formed an alliance with Caria, Persia, and Bactria. Lately he had begun to stir designs on the great Confederacy of Olympia, the more warlike allies of the North. The First Philippic of Demosthenes was spoken in 351 B.C. The Third Philippic—the basis of the extant political speeches—was spoken in 347 B.C. Between these he delivered eight political orations, of which seven are directly concerned with Philip. The whole series falls into two great divisions. The first division comprises three speeches which were spoken against Philip while he was still a foreign power threatening Greece from without. Such are the First Philippic and the three orations for Olympia. The second division comprises the speeches spoken against Philip when by accession to the Amphipolis, and by the capture of Cardia, he had put within the circle of the Greek states, and when the issue was no longer between Greece and Macedonia, but between the Greek and Macedonian parties in Greece. Such are the speech "On the Peace," the speech "On the Embassy," the speech "On the Chersonese," the Second and Third Philippics.

The First Philippic spoken early in 351 B.C. was an oration which was of great importance to an unwarlike people. On the contrary, the Assembly was weary of the subject. For six years the war with Philip had been a theme of barren talk. Demosthenes urges that it is time to disarm and to do it with a plan. Athens fighting Philip has done so long, but an ancient enemy opposed as a settled foe. The business has only suffered delay, while a united eye should have sought them; paucity. An Athenian force must be stationed in the North, at Larissa or Thess. Of 3500 infantry and 200 cavalry in less one quarter must be Athenian citizens capable of disarming the mercenaries.

Later in the same year Demosthenes on another service at the crisis of national freedom. Rhodes severed by its own war from the Athenian Confederacy, had shown

Political
career—
its unity

The political career of Demosthenes, from his first direct contact with public affairs in 355 B.C. to his death in 322, has an essential unity. It is the assertion, in successive forms adapted to successive moments, of unchanging principles. Externally, it is divided into the chapter which precedes and the chapter which follows Chæroneia. But its inner meaning, the secret of its indomitable vigour, the law which harmonizes its apparent contrasts, cannot be understood unless it is regarded as a whole. Still less can it be appreciated in all its large wisdom and sustained self-mastery if it is viewed merely as a duel between the noblest champion and the craftiest enemy of Greek freedom. The time indeed came when Demosthenes and Philip stood face to face as representative antagonists in a mortal conflict. But, for Demosthenes, the special peril represented by Philip, the peril of subjugation to Macedon, was merely a disastrous accident. Philip happened to become the most prominent and most formidable type of a danger which was already threatening Greece before his baleful star arose. As Demosthenes said to the Athenians, if the Macedonian had not existed, they would have made another Philip for themselves. Until Athens recovered something of its old spirit, there must ever be a great standing danger, not for Athens only, but for Greece,—the danger that sooner or later, in some shape, from some quarter—no man could foretell the hour, the manner, or the source—barbarian violence would break up the gracious and undefiled tradition of separate Hellenic life.

The relation
of
Athens to
Greece.

What is the true relation of Athens to Greece? The answer which he gave to this question is the key to the life of Demosthenes. Athens, so Demosthenes held, is the natural head of Greece. Not, however, as an empress holding subject or subordinate cities in a dependence more or less compulsory. Rather as that city which most nobly expresses the noblest attributes of Greek political existence, and which, by her pre-eminent gifts both of intellect and of moral insight, is primarily responsible, everywhere and always, for the maintenance of those attributes in their integrity. Wherever the cry of the oppressed goes up from Greek against Greek, it is the voice of Athens which should first remind the oppressor that Hellene differs from barbarian in postponing the use of force to the persuasions of equal law. Wherever a barbarian hand offers wrong to any city of the Hellenic sisterhood, it is the arm of Athens which should first be stretched forth in the holy strength of Apollo the Averter. Wherever among her own children the ancient loyalty is yielding to love of pleasure or of base gain, there, above all, it is the duty of Athens to see that the central hearth of Hellas is kept pure. Athens must never again seek "empire" in the sense which became odious under the influence of Cleon and Hyperbæus,—when, to use the image of Aristophanes, the allies were as Babylonian slaves grinding in the Athenian mill. Athens must never permit, if she can help it, the re-establishment of such a domination as Sparta exercised in Greece from the battle of Ægospotami to the battle of Lenctra. Athens must aim at leading a free confederacy, of which the members shall be bound to her by their own truest interests. Athens must seek to deserve the confidence of all Greeks alike.

Decay of
public
spirit.

Such, in the belief of Demosthenes, was the part which Athens must perform if Greece was to be safe. But reforms must be effected before Athens could be capable of such a part. The evils to be cured were different phases of one malady. Athens had long been suffering from the profound decay of public spirit. It was of the essence of a Greek commonwealth that the citizen, while perfectly free in his social life, should constantly set his duty to the city above private interests. If the state needs his service in war, he must not hire an inferior substitute to do the work.

If the state requires funds, he must not grudge the money which in quiet times might have been spent on the theatre or the banquet. He must ever remember that, in the phrase of Sophocles, the state is the ship that bears us safe. It does not profit the passenger that his cabin is comfortable if the ship is going down.

Since the early years of the Peloponnesian war, the separation of Athenian society from the state had been growing more and more marked. The old type of the eminent citizen, who was at once statesman and general, had become almost extinct. Politics were now managed by a small circle of politicians. Wars were conducted by professional soldiers whose troops were chiefly mercenaries, and who were usually regarded by the politicians either as instruments or as enemies. The mass of the citizens took no active interest in public affairs. But, though indifferent to principles, they had quickly sensitive partialities for men, and it was necessary to keep them in good humour. Pericles had introduced the practice of giving a small bounty from the Treasury to the poorer citizens, for the purpose of enabling them to attend the theatre at the great festivals,—in other words, for the purpose of bringing them under the concentrated influence of the best Attic culture. A provision eminently wise for the age of Pericles easily became a mischief when the once honourable name of "demagogue" began to mean a flatterer of the mob. Before the end of the Peloponnesian War the festival-money ("theoricon") was abolished. A few years after the restoration of the democracy it was again introduced. But until 354 B.C. it had never been more than a gratuity, of which the payment depended on the Treasury having a surplus. It had never been treated as an annual charge on the revenue, or guaranteed to the citizens as a dividend which they could claim by constitutional right. In 351 B.C. Eubulus became steward of the Treasury. He was an able man, with a special talent for finance, free from all taint of personal corruption, and sincerely solicitous for the honour of Athens, but enslaved to popularity, and without principles of policy. He sought to manage the citizens by humouring to the top of its bent their disinclination for personal sacrifice, and their preference for public show to public strength. More than any other one man, Eubulus represents that new, easy-going, improvident Athens in which the vigilant civic spirit was dead. His first measure was to make the festival-money a permanent item in the budget. Thenceforth this bounty was in reality very much what Demades afterwards called it,—the cement (κόλλα) of the democracy.

Years before the danger from Macedon was urgent, Demosthenes had begun the work of his life,—the effort to lift the spirit of Athens, to revive the old civic loyalty, to rouse the city into taking that place and performing that part which her own welfare as well as the safety of Greece prescribed. His formally political speeches must never be considered apart from his forensic speeches in public causes. The Athenian procedure against the proposer of an unconstitutional law—i.e., of a law incompatible with existing laws—had a direct tendency to make the law court, in such cases, a political arena. The same tendency was indirectly exerted by the tolerance of Athenian juries (in the absence of a presiding expert like a judge) for irrelevant matter, since it was usually easy for a speaker to make capital out of the adversary's political antecedents. But the forensic speeches of Demosthenes for public causes are not only political in this general sense. They are documents, as indispensable as the Olynthiacs or Philipics, for his own political career. Only by taking them along with the formally political speeches, and regarding the whole as one unbroken series, can we see clearly the full scope of the task which he set before him,—a task in which his long

resistance to Philip was only the most dramatic incident, and in which his real achievement is not to be measured by the event of Chæronea.

355 B.C.
"Against Andro-
tion"

A forensic speech, composed for a public cause, opens the political career of Demosthenes with a protest against a signal abuse. In 355 B.C., at the age of twenty-nine, he wrote the speech "Against Androton." This combats on legal grounds a proposal that the outgoing Senate should receive the honour of a golden crown. In its larger aspect, it is a denunciation of the corrupt system which that Senate represented, and especially of the manner in which the Treasury had been administered by Aristophon. In 354 B.C. Demosthenes composed and spoke the oration "Against Leptines," who had effected a slender saving for the state by the expedient of revoking those hereditary exemptions from taxation which had at various times been conferred in recognition of distinguished merit. The descendants of Harmodius and Aristogeiton alone had been excepted from the operation of the law. This was the first time that the voice of Demosthenes himself had been heard on the public concerns of Athens, and the utterance was a worthy prelude to the career of a statesman. He answers the advocates of the retrenchment by pointing out that the public interest will not ultimately be served by a wholesale violation of the public faith. In the same year he delivered his first strictly political speech. The Athenians, irritated by the support which Artaxerxes had lately given to the revolt of their allies, and excited by rumours of his hostile preparations, were feverishly eager for a war with Persia. Demosthenes urges that such an enterprise would at present be useless; that it would fail to unite Greece; that the energies of the city should be reserved for a real emergency; but that, before the city can successfully cope with any war, there must be a better organization of resources, and, first of all, a reform of the navy. The scheme of naval reform which he propounds has characteristic exactness of detail. We see how closely he has thought out the question. The same practical and luminous precision is a striking trait in every speech of Demosthenes which recommends a course of action.

354 B.C.
"On the Navy
Boards"

352 B.C.
"For the Megalo-
politans"

Two years later he is found dealing with a more definite question of foreign policy. Sparta, favoured by the depression of Thebes in the Phocian war, was threatening Megalopolis. Both Sparta and Megalopolis sent embassies to Athens. Demosthenes supported Megalopolis. The ruin of Megalopolis would mean, he argued, the return of Spartan domination in the Peloponnese. Athenians must not favour the tyranny of any one city. They must respect the rights of all the cities, and thus promote unity based on mutual confidence. In the same year Demosthenes wrote the speech "Against Timocrates," to be spoken by the same Diodorus who had before prosecuted Androton, and who now combated an attempt to screen Androton and others from the penalties of embezzlement. The speech "Against Aristocrates," also of 352 B.C., reproves that foreign policy of feeble make-shifts which was now popular at Athens. The Athenian tenure of the Thracian Chersonese partly depended for its security on the goodwill of the Thracian prince Cersobleptes. Charidemus, a soldier of fortune who had already played Athens false, was now the brother-in-law and the favourite of Cersobleptes. Aristocrates proposed that the person of Charidemus should be invested with a special sanctity, by the enactment that whoever attempted his life should be an outlaw from all dominions of Athens. Demosthenes points out that such adulation is as futile as it is fulsome. Athens can secure the permanence of her foreign possessions only in one way—by being strong enough to hold them.

crates."

Principles of policy.

must be purified. Statesmen must be made to feel that they are responsible to the state. They must not be allowed to anticipate judgment on their deserts by voting each other golden crowns. They must not think to screen misappropriation of public money by getting partisans to pass new laws about state-debtors. Foreign policy must be guided by a larger and more provident conception of Athenian interests. When public excitement demands a foreign war, Athens must not rush into it without asking whether it is necessary, whether it will have Greek support, and whether she herself is ready for it. When a strong Greek city threatens a weak one, and seeks to purchase Athenian connivance with the bribe of a border-town, Athens must remember that duty and prudence alike command her to respect the independence of all Greeks. When it is proposed, by way of insurance on Athenian possessions abroad, to flatter the favourite of a doubtful ally, Athens must remember that such devices will not avail a power which has no army except on paper, and no ships fit to leave their moorings.

But the time had gone by when Athenians could have tranquil leisure for domestic reform. A danger, calling for prompt action, had at last come very near. For six years Athens had been at war with Philip on account of his seizure of Amphipolis. Meanwhile he had destroyed Potidæa and founded Philippi. On the Thracian coasts he had become master of Abdera and Maronea. On the Thessalian coast he had acquired Methone. In a second invasion of Thessaly, he had overthrown the Phocians under Onomarchus, and had advanced to Thermopylæ, to find the gates of Greece closed against him by an Athenian force. He had then marched to Heræon on the Propontis, and had dictated a peace to Cersobleptes. He had formed an alliance with Cardia, Perinthus, and Byzantium. Lastly, he had begun to show designs on the great Confederacy of Olynthus, the more warlike Miletus of the North. The First Philippic of Demosthenes was spoken in 351 B.C. The Third Philippic—the latest of the extant political speeches—was spoken in 341 B.C. Between these he delivered eight political orations, of which seven are directly concerned with Philip. The whole series falls into two great divisions. The first division comprises those speeches which were spoken against Philip while he was still a foreign power threatening Greece from without. Such are the First Philippic and the three orations for Olynthus. The second division comprises the speeches spoken against Philip when, by admission to the Amphictyonic Council, he had now won his way within the circle of the Greek states, and when the issue was no longer between Greece and Macedonia, but between the Greek and Macedonian parties in Greece. Such are the speech "On the Peace," the speech "On the Embassy," the speech "On the Chersonese," the Second and Third Philipics.

The First Philippic, spoken early in 351 B.C., was no sudden note of alarm drawing attention to an unnoticed peril. On the contrary, the Assembly was weary of the subject. For six years the war with Philip had been a theme of barren talk. Demosthenes urges that it is time to do something, and to do it with a plan. Athens fighting Philip has fared, he says, like an amateur boxer opposed to a skilled pugilist. The helpless hands have only followed blows which a trained eye should have taught them to parry. An Athenian force must be stationed in the north, at Lemnos or Thasos. Of 2000 infantry and 200 cavalry at least one quarter must be Athenian citizens capable of directing the mercenaries.

Later in the same year Demosthenes did another service to the cause of national freedom. Rhodes, severed by its own act from the Athenian Confederacy, had since 355

Athens and Philip

been virtually subject to Mausolus, prince (δυναστεύς) of Caria, himself a tributary of Persia. Mausolus died in 351, and was succeeded by his widow Artemisia. The democratic party in Rhodes now appealed to Athens for help in throwing off the Carian yoke. Demosthenes supported their application. No act of his life was a truer proof of statesmanship. He failed. But at least he had once more warned Athens that the cause of political freedom was everywhere her own, and that, wherever that cause was forsaken, there a new danger was created both for Athens and for Greece.

Next year an Athenian force under Phocion was sent to Eubœa, in support of Plistarchus, tyrant of Eretria, against the faction of Clitarchus. Demosthenes protested against spending strength, needed for greater objects, on the local quarrels of a despot. Phocion won a victory at Tamynæ. But the "inglorious and costly war" entailed an outlay of more than £12,000 on the ransom of captives alone, and ended in the total destruction of Athenian influence throughout Eubœa. That island was now left an open field for the intrigues of Philip. Worst of all, the party of Eubulus not only defeated a proposal, arising from this campaign, for applying the festival-money to the war-fund, but actually carried a law making it high treason to renew the proposal. The amusement of the citizens was thus officially declared to be more important than the protection of their properties or lives, and the expression of a different opinion was henceforth to be a crime. The degree to which political enmity was exasperated by the Eubœan war may be judged from the incident of Midias, an adherent of Eubulus, and a type of that opulent rowdiness which shows how curiously loose the hold of the state had now become on men who were not restrained by regard for their purses or their characters. Demosthenes was choragus of his tribe, and was wearing the robe of that sacred office at the great festival in the theatre of Dionysus, when Midias struck him on the face. The affair was eventually compromised. The speech written by Demosthenes for the trial was neither spoken nor completed, and remains, as few will regret, a sketch.

It was now three years since, in 352, the Olynthians had sent an embassy to Athens, and had made peace with their only sure ally. In 350 a second Olynthian embassy had sought and obtained Athenian help. The hour of Olynthus had indeed come. In 349 Philip opened war against the Chalcidic towns of the Olynthian League. The First and Second Olynthiacs of Demosthenes were spoken in that year. "Better now than later," is the thought of the First Olynthiac. "The fight must come. Better that it should be fought in Macedonia than in Attica. Everything favours us now. Send one force to defend Olynthus, and another to attack Philip." The Second Olynthiac argues that Philip's strength is overrated. "He is weak in so far as he is selfish and unjust. He is strong only because he is energetic. Let us be energetic too, and our just cause will prevail." The Third Olynthiac—spoken in 348—carries us into the midst of action. It deals with practical details. The festival-fund must be used for the war. The citizens must serve in person. A few months later, Olynthus and the thirty-two towns of the Confederacy were swept from the earth. Men could walk over their sites, Demosthenes said seven years afterwards, without knowing that such cities had existed. It was now certain that Philip could not be stopped outside of Greece. The question was, What point within Greece shall he be allowed to reach?

Eubulus and his party, with that versatility which is the privilege of political vagueness, now began to call for a congress of the allies to consider the common danger. They found a brilliant interpreter in Æschines, who, after having been a tragic actor and a clerk to the assembly, had entered

political life with the advantages of a splendid gift for eloquence, a fine presence, a happy address, a ready wit, and a facile conscience. While his opponents had thus suddenly become warlike, Demosthenes had become pacific. He saw that Athens must have time to collect strength. Nothing could be gained, meanwhile, by going on with the war. Macedonian sympathizers at Athens, of whom Philocrates was the chief, also favoured peace. Eleven envoys, including Philocrates, Æschines, and Demosthenes, were sent to Philip in February, 346 B.C. After a debate at Athens, peace was concluded with Philip in April. Philip on the one hand, Athens and her allies on the other, were to keep what they respectively held at the time when the peace was ratified. But here the Athenians made a fatal error. Philip was bent on keeping the door of Greece open. Demosthenes was bent on shutting it against him. Philip was now at war with the people of Halus in Thessaly. Thebes had for ten years been at war with Phœcia. Here were two distinct chances for Philip's armed intervention in Greece. But if the Halians and the Phœcians were included in the peace, Philip could not bear arms against them without violating the peace. Accordingly Philip insisted that they should not be included. Demosthenes insisted that they should be included. They were not included. The result followed speedily. The same envoys were sent a second time to Philip for the purpose of receiving his oaths in ratification of the peace. It was late in June before he returned from Thracia to Pella—thus gaining, under the terms, all the towns that he had taken meanwhile. He next took the envoys with him through Thessaly to Thermopylæ. There—at the invitation of Thessalians and Thebans—he intervened in the Phœcian war. Phœceus surrendered. Phœcia was crushed. Philip took its place in the Amphictyonic Council, and was thus established as a Greek power in the very centre, at the sacred hearth, of Greece. The right of precedence in consultation of the oracle (ἐπαρχεία) was transferred from Athens to Philip. While indignant Athenians were clamouring for the revocation of the peace, Demosthenes upheld it. It ought never to have been made on such terms, he said. But, having been made, it had better be kept. "If we went to war now, where should we find allies? And after losing Oropus, Amphipolis, Cardia, Chios, Cos, Rhodes, Byzantium, shall we fight about the shadow of Delphi?"

During the eight years between the peace of Philocrates and the battle of Chæronea, the authority of Demosthenes steadily grew, until it became first predominant and then paramount. He had, indeed, a melancholy advantage. Each year his argument was more and more cogently enforced by the logic of facts. In 344 he visited the Peloponnesus for the purpose of counteracting Macedonian intrigue. Mistrust, he told the Peloponnesian cities, is the safeguard of free communities against tyrants. Philip lodged a formal complaint at Athens. Here, as elsewhere, the future master of Greece reminds us of Napoleon on the eve of the First Empire. He has the same imperturbable and persuasive effrontery in protesting that he is doing one thing at the moment when his energies are concentrated on doing the opposite. Demosthenes replied in the Second Philippic. "If," he said, "Philip is the friend of Greece, we are doing wrong. If he is the enemy of Greece, we are doing right. Which is he? I hold him to be our enemy, because everything that he has hitherto done has benefited himself and hurt us." The prosecution of Æschines for malversation on the embassy, which was brought to an issue in the following year, marks the moral strength of the position now held by Demosthenes. When the gravity of the charge and the complexity of the evidence are considered, the acquittal of Æschines by a narrow majority

must be deemed his condemnation. The speech "On the Affairs of the Chersonese," and the Third Philippic, were the crowning efforts of Demosthenes. Spoken in the same year, 341 B.C., and within a short space of each other, they must be taken together. The speech "On the Affairs of the Chersonese" regards the situation chiefly from an Athenian point of view. "If the peace means," argues Demosthenes, "that Philip can seize with impunity one Athenian possession after another, but that Athenians shall not on their peril touch aught that belongs to Philip, where is the line to be drawn? We shall go to war, I am told, when it is necessary. If the necessity has not come yet, when will it come?" The Third Philippic surveys a wider horizon. It ascends from the Athenian to the Hellenic view. Philip has annihilated Olynthus and the Chalcidic towns. He has ruined Phocis. He has frightened Thebes. He has divided Thessaly. Eubœa and the Peloponnesus are his. His power stretches from the Adriatic to the Hellespont. Where shall be the end? Athens is the last hope of Greece. And, in this final crisis, Demosthenes was the embodied energy of Athens. It was Demosthenes who went to Byzantium, brought the estranged city back to the Athenian alliance, and snatched it from the hands of Philip. It was Demosthenes who, when Philip had already seized Elatea, hurried to Thebes, who by his passionate appeal gained one last chance, the only possible chance, for Greek freedom, who broke down the barrier of an inveterate jealousy, who brought Thebans to fight beside Athenians, and who thus won at the eleventh hour a victory for the spirit of loyal union which took away at least one bitterness from the unspeakable calamity of Chæronea.

cipal
activity.

But the work of Demosthenes was not closed by the ruin of his cause. During the last sixteen years of his life he rendered services to Athens not less important, and perhaps more difficult, than those which he had rendered before. He was now, as a matter of course, foremost in the public affairs of Athens. In January 337, at the annual winter Festival of the Dead in the Outer Cermæicus, he spoke the funeral oration over those who had fallen at Chæronea. He was member of a commission for strengthening the fortifications of the city (τειχοποιός). He administered the festival-fund. During a dearth which visited Athens between 330 and 326 he was charged with the organization of public relief. In 324 he was chief (ἀρχιθέωρος) of the sacred embassy to Olympia. Already, in 336, Ctesiphon had proposed that Demosthenes should receive a golden crown from the state, and that his extraordinary merits should be proclaimed in the theatre at the Great Dionysia. The proposal was adopted by the Senate as a bill (προβουλευμα); but it must be passed by the Assembly before it could become an act (ψήφισμα). To prevent this, Æschines gave notice, in 336, that he intended to proceed against Ctesiphon for having proposed an unconstitutional measure. For six years Æschines avoided action on this notice. At last, in 330, the patriotic party felt strong enough to force him to an issue. Æschines spoke the speech "Against Ctesiphon," an attack on the whole public life of Demosthenes. Demosthenes gained an overwhelming victory for himself and for the honour of Athens in the most finished, the most splendid, and the most pathetic work of ancient eloquence—the immortal oration "On the Crown."

Affair of
Harpalus.

In the winter of 325-4 Harpalus, the receiver-general of Alexander in Asia, fled to Greece, taking with him 8000 mercenaries, and treasure equivalent to about a million and a quarter sterling. On the motion of Demosthenes he was warned from the harbours of Attica. Having left his troops and part of his treasure at Tenarum, he again presented himself at the Peiræus, and was now

admitted. He spoke fervently of the opportunity which offered itself to those who loved the freedom of Greece. All Asia would rise with Athens to throw off the hated yoke. Fiery patriots like Hyperides were in raptures. For zeal which could be bought Harpalus had other persuasions. But Demosthenes stood firm. War with Alexander would, he saw, be madness. It could have but one result,—some indefinitely worse doom for Athens. Antipater and Olympias presently demanded the surrender of Harpalus. Demosthenes opposed this. But he reconciled the dignity with the loyalty of Athens by carrying a decree that Harpalus should be arrested, and that his treasure should be deposited in the Parthenon, to be held in trust for Alexander. Harpalus escaped from prison. The amount of the treasure, which Harpalus had stated as 700 talents, proved to be no more than 350. Demosthenes proposed that the Areopagus should inquire what had become of the other 350. Six months, spent in party intrigues, passed before the Areopagus gave in their report (ἀπόφασις). The report implicated nine persons. Demosthenes headed the list of the accused. Hyperides was among the ten public prosecutors. Demosthenes was condemned, fined fifty talents, and, in default of payment, imprisoned. After a few days he escaped from prison to Ægina, and thence to Træzen. Two things in this obscure affair are beyond reasonable doubt. First, that Demosthenes was not bribed by Harpalus. The hatred of the Macedonian party towards Demosthenes, and the fury of those vehement patriots who cried out that he had betrayed their best opportunity, combined to procure his condemnation, with the help, probably, of some appearances which were against him. Secondly, it can hardly be questioned that, by withstanding the hot-headed patriots at this juncture, Demosthenes did heroic service to Athens.

Next year Alexander died. Then the voice of Demosthenes, calling Greece to arms, rang out like a trumpet. Early in August 322, the battle of Crannon decided the Lamian war against Greece. Antipater demanded, as the condition on which he would refrain from besieging Athens, the surrender of the leading patriots. Demades moved the decree of the Assembly by which Demosthenes, Hyperides, and some others were condemned to death as traitors. On the 20th of Boedromion (September 16) 322, a Macedonian garrison occupied Munychia. It was a day of solemn and happy memories, a day devoted, in the celebration of the Great Mysteries, to sacred joy,—the day on which the glad procession of the Initiated returned from Eleusis to Athens. It happened, however, to have another association, more significant than any ironical contrast for the present purpose of Antipater. It was the day on which, thirteen years before, Alexander had punished the rebellion of Thebes with annihilation.

The condemned men had fled to Ægina. Parting there from Hyperides and the rest, Demosthenes went on to Calauria, a small island off the coast of Argolis. In Calauria there was an ancient temple of Poseidon, once a centre of Mityan and Iouan worship, and surrounded with a peculiar sanctity as having been, from time immemorial, an inviolable refuge for the pursued. Here Demosthenes sought asylum. Archias of Thurii, a man who, like Æschines, had begun life as a tragic actor, and who was now in the pay of Antipater, soon traced the fugitive, landed in Calauria, and appeared before the temple of Poseidon with a body of Thracian spearmen. Plutarch's picturesque narrative bears the marks of artistic elaboration. Demosthenes had dreamed the night before that he and Archias were competing for a prize as tragic actors; the house applauded Demosthenes; but his chorus was shabbily equipped, and Archias gained the prize. Archias was not the man to stick at sacrilege. In Ægina,

image the majesty of the state, and enforce weighty counsels with lofty and impassioned fervour. A true artist, he grudged no labour which could make the least part of his work more perfect. Isocrates spent ten years on the *Panegyricus*. After Plato's death, a manuscript was found among his papers with the first eight words of the *Republic* arranged in several different orders. What wonder, then, asks the Greek critic, if the diligence of Demosthenes was no less incessant and minute? "To me," he says, "it seems far more natural that a man engaged in composing political discourses, imperishable memorials of his power, should neglect not even the smallest details, than that the veneration of painters and sculptors, who are darkly showing forth their manual tact and toil in a corruptible material, should exhaust the refinements of their art on the veins, on the feathers, on the down of the lip, and the like niceties." It may be surmised that much of the admiration professed for Demosthenes in modern times has been conventional. The clumsiest and coarsest forgeries which bear his name long received among general readers their share of the eulogy. A soundly critical study of his text is not yet sixty years old. To this day popular books occasionally show traces of the notion that everything which the manuscripts ascribe to him was written by him. But modern study has long since learned to recognize the surest traits of his style; not, indeed, with the exquisite perception of his old Greek critics, yet sufficiently, as a rule, for the discrimination of genuine work from false, and on a firmer diplomatic basis. The modern world can never catch again the finer tones of that great music as they still echoed on the ear of Greece in her calm after-time—

when all the winds were laid,
And every height came out, and jutting peak
And valley, and the immeasurable heavens
Broke open to their highest;

but men can still hear the voice of a prophet whose resonant warnings rise above confused sounds of strife, they can still feel the energy, the anguish, the indignation which vibrate through his accents; and they can acknowledge, with an admiration undiminished by the lapse of twenty centuries, the power of his words to quicken the sense of honour in craven hearts, to raise the votaries of selfish luxury to the loyalty of prolonged self-sacrifice, to nerve irresolute arms for an inevitable struggle, and, when all has been lost, to sustain the vanquished with the thought that, though a power above man has forbidden them to prevail, yet their suffering has saved the lustre of a memory which they were bound to guard, and has left them pure before the gods.

Works.

More than half of the sixty-one speeches extant under the name of Demosthenes are certainly or probably spurious. Much difference of opinion still exists in particular cases, especially as regards two or three of the private speeches. The results to which the preponderance of opinion now leans are given in the following table. Those marked *a* were already rejected or doubted in antiquity, those marked *m*, first in modern times.—

Or 60 (*ἐπιτάφιος*) and Or 61 (*ἐρωτικός*) are works of rhetoricians. The six epistles are also forgeries; they were used by the composer of the twelve epistles which bear the name of Æschines. The 56 *προοίμια*, exordia or sketches for political speeches, are by various hands and of various dates. They are valuable as being compiled from Demosthenes himself, or from other classical models.

The ancient fame of Demosthenes as an orator can be compared only with the fame of Homer as a poet. Cicero, with generous appreciation, recognizes Demosthenes as the standard of perfection. Dionysius, the closest and most penetrating of his ancient critics, exhausts the language of admiration in showing how Demosthenes united and elevated whatever had been best in earlier masters of the Greek idiom. Hermogenes, in his works on rhetoric, refers to Demosthenes, as *ὁ πρῶτος*, the orator. The writer of the treatise On Sublimity knows no heights loftier than those to which Demosthenes has risen. From his own younger contemporaries, Aristotle and Theophrastus, who founded their theory of rhetoric in large part on his

Literary history of Demosthenes.

tion when serious illness required that he should leave Rome for change of climate. By way of Switzerland, he travelled to the Netherlands, and made a short stay at Tournay, to which he returned to teach humanity after a period of study at the university of Douai, where he distinguished himself in poetical and philosophical competitions, and took the degree of M.A. As his prospects in Tournay were discouraging, he went back to Paris, graduated as doctor of canon law, and became a regent in the college of Navarre, while yet, as he himself states, in his seventeenth year. Destined to be a wanderer through life, he soon quitted Paris to settle in Toulouse, where his stay was shortened by certain influential individuals, whose resentment he had excited by his advocacy of university rights. At Nîmes, his next resting-place, he was, by twenty-three of the twenty-four judges, chosen to the professorship of eloquence in the Protestant university or academy, which circumstance colours in some degree the conjecture of Bayle, that his zeal for the Romish faith had somewhat cooled. Having retained his chair for little more than the two years of litigation into which he had been dragged by one of the unsuccessful candidates who had libellously assailed him, and against whom the Parliament of Toulouse decided, Dempster made a journey into Spain, whence, after a brief engagement as preceptor to a son of the famous Saint-Luc, he departed for his native land. As he did not experience a favourable reception either from his relatives or from the clergy, he remained but a short time, and again betook himself to Paris. There he spent seven years with advantage to his reputation and purse, as regent in different colleges. His connection with that of Beauvais, over which he presided for a time, was brought to a close by a high-handed procedure illustrative of his fierce courage, and suggestive of his fitness for other than literary contests. In the year 1615 he accepted the invitation of King James to come to London, and was honoured and rewarded by that sovereign. But disappointed of preferment, which clerical and episcopal prejudices influenced the king to withhold, he again left England for Italy. On his arrival in Rome he was at first suspected of being a spy, but when his claims were ascertained, he was so fortunate as to receive letters of recommendation from the Pope and other influential personages to the duke of Tuscany, which issued in his appointment to the professorship of the Pandects in the university of Pisa. Writings of this date attest his competency for the chair. After his inaugural lecture his reputation and emoluments increased. In the following year, on a visit to England, his disputatious spirit brought him into collision with an English ecclesiastic, whose representation of the quarrel led the grand duke to require that Dempster should either apologize or leave the country. Rather than make the prescribed apology he quitted Florence with the intention of settling in Scotland; but he was prevailed upon by Cardinal Capponi to stay at Bologna, and in a few days, by the influence of the cardinal, was appointed to the chair of humanity, which he filled with the utmost efficiency and increase of fame. Honours, civil and literary, were bestowed upon him, and it seemed as if his wanderings and reverses had together come to an end. But the crowning calamity of his life then befell him. His light-headed wife (he married her in London in 1615), whose beauty had always been a snare to her, eloped with one of his students; and the mental distress and bodily fatigue consequent on his pursuit of the fugitives, during the dog days, predisposed him to fever, which attacked him and proved fatal. He died at Bologna in 1625, in his forty-sixth year. Morally his chief defect was the fierceness of his temperament, which involved him in many broils, and made his sword and pen alike formidable. His natural impetuosity, which so easily broke forth in ebul-

litions of violence, explains in large measure the looseness and rocklessness of statement often found in his writings. His intellectual qualifications entitle him to be considered "one of the most learned men whom Scotland has produced." A vast memory, which was the receptacle of many books, an extraordinary familiarity with Greek and Latin, that enabled him to improvise verses in these tongues with the utmost rapidity; and a versatility which made versification, philological discussions, classical criticism, juridical expositions, biographical narratives, and historical annals congenial to him,—these endowments gave him a high place among the learned. The defects of his writings were mainly due to the passionateness which often clouded his judgment, to a patriotic vanity that led to absurd exaggerations on Scotch subjects, and to the disturbing influence of a restless life. For list of his very numerous writings see *Irving's Lives of the Scottish Writers*.

DEMURRAGE, in the law of merchant shipping, is the sum payable by the freighter to the shipowner for detention of the vessel in port beyond the number of days allowed for the purpose of loading or unloading. The contract between the parties generally specifies the amount per day to be paid as demurrage, and the number of days for which the ship may be detained at that rate. If it should be detained longer than the specified time of demurrage, the freighter will be entitled to damages, the measure of which will (in general, but not necessarily) be the sum agreed upon between the parties for demurrage. If no time is specified for unloading a ship, the "usual customary time" will be implied. But when there is positive contract that the goods are to be taken out by a fixed day, any delay beyond that time, not caused by the act of the shipowner himself, will make the freighter liable for demurrage, whether the delay is caused by him or not. So an agreement to load, not mentioning time, according to the customary manner, is an agreement to load within a reasonable time according to the usage of the port, and any delay beyond that time, though caused by circumstances beyond the control of the freighters, will make them liable. In calculating the number of *lay-days* (i.e., the days allowed for loading, &c., and not chargeable with demurrage), Sundays will be taken into account, unless it is otherwise specified or there is a custom to the contrary. The contract to pay demurrage in a charter-party is between the freighters and the shipowner, but if demurrage is mentioned in the bill of lading, the consignee will be held to take the goods under an implied obligation to pay the demurrage, and the master may sue for it in his own name. See **CHARTER-PARTY**.

DEMURRER, in English law, is an objection taken to the sufficiency, in point of law, of the pleading or written statement of the other side. In equity pleading a demurrer lay only against the bill, and not against the answer, at common law any part of the pleading could be demurred to. And now in all cases any party may demur to any pleading of the opposite party, or to any part of a pleading setting up a distinct cause of action, ground of defence, set off, counter-claim, reply, or as the case may be, on the ground that the facts alleged therein do not show any cause of action or ground of defence, &c. (Judicature Act, 1875—Rules of Court, Order 28).

DENAIN, a town of France, in the department of Nord, and arrondissement of Valenciennes, 14 miles to the east of Douai, on the Scheldt Canal and the railway between Anzin and Somain. A mere village in the beginning of the present century, it has rapidly increased since 1850, and now, according to the census of 1872, possesses about 10,500 inhabitants, who are mainly engaged in coal mines, iron-smelting works, sugar factories, and distilleries. The village was the scene of the decisive victory gained, in

1712, by Marshal Villars over the allies commanded by Prince Eugene, and the battle-field is marked by a monolithic monument inscribed with the verses of Voltaire—

Regardez dans Denain l'audacieux Villars
Disputant le tonnerre à l'angle des Césars.

DENBIGH, a maritime county of North Wales, is about 40 miles in its extreme length from N.W. to S.E., by 36 at its greatest and 8 at its least width, where it is divided into two unequal portions. It embraces a superficial area of 392,005 statute acres, or 612½ square miles. The population in 1871 amounted to 105,102 persons, 52,866 males and 52,236 females; in 1861 it numbered 100,778, and in 1851, 92,583. The county was formed 27 Hen. VIII., out of the lordships of Denbigh, Ruthin, Rhos, and Rhyfoniog, corresponding roughly with the district called *Perfeddwlad* (or the midland between the Conway and the Clwyd), and the lordships of Bromfield, Yale, and Chirkland, which at an earlier period had been comprised in the possessions of Gruffydd ap Madoc, the lord of Dinas Bran. It is bounded on the W. in its northern division by the River Conway, from one of its ancient mouths in Llandrillo Bay to its source in the Migneint mountains, in the southern by the Berwyn chain, and on its extreme E. by the line of the Dee, the Ceiriog, and a portion of Offa's Dyke. The intervening surface is very irregular, and its physical character highly diversified. The N.W. portion is occupied by the bleak, bare table-land of the Hiraethog hills, which slope on the west to the valley of the Conway and on the east to the Vale of Clwyd, by which they are divided from the Clwydian range and the hills of Yale. On the N. it stretches along the bays of Colwyn and Abergelle, and on the S. it is separated from Merionethshire by the Ysphyty and Llangwm range. From this watershed flow tributaries of the Clwyd, the Conway, and the Dee—viz., the Elwy, the Aled, the Clywedog, the Merddwr, and the Alwen. The valleys along which some of these streams flow are, from their fertility and natural beauty, in striking contrast to their bleak surroundings. Among these may be specified the beautiful gorge of the Elwy and the broad fertile plain of the Vale of Clwyd. Of the other division, which extends from near Farnon Bridge in the N.E. to the Rhaidr in Mochnant S.W., that portion which lies between the Rhuaabon hills and the Dee is extremely rich in minerals as well as in agricultural produce; the other portion, from the Berwyn to Offa's Dyke, is comparatively wild and barren, save the pretty valley of the Tanat, the cup-like plain of Llansilin, and the lower reaches of the Ceiriog. One of the feeders of the Tanat rolls down a waterfall named Pistyll Rhaidr, which is 240 feet high, and another rises in the little lake of "Llyncaws," which nestles beneath Moel Syeh, 2716 feet, the highest point in the Berwyn range, and indeed in the county. There are also a few lakes in the Hiraethog district, the largest of which—Aled and Alwen—give rise to rivers of the same names.

Soil and Agriculture—On the uplands the soil is too cold and poor, and the seasons too uncongenial, to admit of good corn crops; but a more profitable investment is made in the rearing of mountain ponies and of sheep and black cattle, which are sold in great numbers to be fattened in the Midland Counties of England, for the London market. Less than a third of the surface is under cultivation; and the agricultural acreage was thus distributed in the years 1873 and 1876:—

	Corn Crops.	Green Crops.	Grass under rotation.
1873	65,488	15,461	41,699
1876	61,416	14,334	42,337

Of the corn crops, oats occupy much the largest amount of acreage, and of green crops, turnips.

The live stock of the county in the same years was distributed thus:—

	Cattle.	Sheep.	Pigs.	Horses.
1873	58,122	273,721	24,240	11,395
1876	56,976	258,464	24,438	11,789

In the valleys, and indeed far up the sunny slopes of the hills, the latest improvements in agriculture may be observed, and the reaping hook and the flail are fast disappearing before the reaping and the thrashing machines. This progress has been largely due to several Farmers' Clubs, such as the Denbighshire and Flintshire, the Vale of Conway, and the Cerrigydrudion. But the railways have done still more. The Vale of Llanrwst, the Vale of Clwyd, and the Denbigh and Chester lines have linked their respective districts to the great trunk line of the London and North Western; whilst the Denbigh, Ruthin, and Corwen, the Corwen and Rhuaabon, the Wrexham and Connah's Quay, and yet again the Rhos-llanerehrugog and the Glyn Ceiriog tramways, have done the same for the Great Western,—thus opening all the main arteries of the county alike to external and internal communication, and vastly developing its resources. Down the picturesque Vale of Llangollen also runs the great Holyhead Road—in its day the principal means of communication between London and Ireland, and for engineering skill, excellency of workmanship, and beauty of scenery probably still unsurpassed in the United Kingdom.

The *geology* of the county is full of interest, as it develops all the principal strata that intervene between the Lower Silurian and the Triassic series. In the Lower Silurian district, which extends from the southern boundary to the Ceiriog, the Llandeilo formation of the eastern slopes of the Berwyn and the Bala beds of shelly sandstone are traversed east and west by bands of intrusive felspathic porphyry and ashes; northwards from the Ceiriog to the limestone fringe at Llandrillo, the Wenlock shale of the Upper Silurian covers the entire mass of the Hiraethog and Clwydian hills, but verging on its western slopes into the Denbighshire grit, which may be traced southward in a continuous line from the mouth of the Conway as far as Llanddewi Ystrad Enni in Radnorshire. On its eastern slope a narrow broken band of the Old Red crops up along the Vale of Clwyd and in Eglwysseg. Resting upon this the Carboniferous Limestone extends from Llanymynach, its extreme southern point, to the Cynybrain fault, and there forks into two divisions that terminate respectively in the Great Orme's Head and in Talargoeh, and are separated from each other by the denuded shales of the Moel Famma range. In the Vale of Clwyd the limestone underlies the New Red Sandstone, and in the eastern division it is itself overlaid by the millstone grit of Rhuaabon and Minera, and by a long reach of the coal measures which near Wrexham are 4½ miles in breadth. Eastward of these a broad strip of the Permian succeeds, and yet again between this and the Dee the ground is occupied—as in the Vale of Clwyd—by the New Red.

The *mineral resources* of the county under these conditions are naturally considerable. Paving flags are raised at Nantglyn; slates and slabs for ornamental purposes, on a large scale, on Rhiwfelen, near Llangollen; and slates at Glyn Ceiriog. The limestone is used largely, and exported extensively for building, fluxing, and agricultural purposes; and at Brymbo there is a fine layer of China stone. The sandstones of Cefn Rhuaabon are wrought into grindstones, and the grit is used for millstones. The coal measures at Chirk, Rhuaabon, and Brymbo are very productive, the number of collieries in 1875 being 61, and the quantity raised annually estimated at 1,379,560 tons. In close contiguity to the coal seams, ironstone is found, and the six furnaces in

blast at Rhuabon and at Brymbo (where John Wilkinson was the first to introduce the industry) produced (together with one in Flintshire) in the same year 55,099 tons of pig iron, valued at £232,000. Lead ore is another and still more important item; the most productive mine has been the Great Minera, which yields profits of about £30,000 a year. The seven mines in the county produced, in 1875, 2600 tons of lead ore, 1954 tons of lead, and 10,873 ounces of silver. One of the latest industries introduced has been the manufacture of dynamite in the valley of the Ceiriog. At the village of Llangantffraid, and at Llangollen, there are woollen factories.

The principal towns are Wrexham (population 8576), the centre of the mining district, noted for its beautiful church tower, and recently selected as the military centre for North Wales; Denbigh, the nominal capital (4276), notable for its castle ruins and Howell's female orphan school, Ruthin (3298), where the assizes are held, famous for its grammar school and its fine castle lately rebuilt; Llangollen, with its beautiful scenery; Llanrwst, with its church monuments and rood-loft, its bridge, and salmon fishing; and Holt, with its ancient ruined castle.

As regards the ownership of the land, the county (in 1873) was divided among 5708 separate proprietors, whose total rental was estimated at £450,421. Of the owners 3436, or 60 per cent., held less than 1 acre, about the same proportion as in the neighbouring county of Flint; while the average of small proprietors in all England was 71 per cent. The average property amounted to 61 acres, while that of all England was 34, and the average value per acre was £1, 5s 3d., as against £3, 0s. 2d. for all England.

The following proprietors held more than 5000 acres in the above year—viz., Sir Watkin W. Wynn, 33,998 acres; J. L. Wynne, Coed Cêch, 10,197; Lord Bagot, Pool Park, 9385; H. R. Hughes, Kinnel, 8561; C. W. Finch, Pentrefoelas, 8025; B. W. Wynne, Garthefwin, 6435; C. S. Mainwaring, Galltfaenan, 6428; R. M. Biddulph, Chirk Castle, 5513; W. C. West, Ruthin Castle, 5457, and Sir Hugh Williams, Bodelwyddan, 5360.

For civil purposes, the county is divided into 6 hundreds, 9 petty sessional divisions, 3 police districts, 5 highway districts, and 9 lieutenancy subdivisions; and it forms a part of the North Wales circuit, with a winter assize. For parliamentary purposes the county is an undivided constituency, returning two representatives to Parliament, while the contributory boroughs of Denbigh, Ruthin, Wrexham, and Holt return one member. Ecclesiastically the county lies entirely within the diocese of St Asaph, the number of parishes and ecclesiastical districts is 61, comprised under 6 deaneries within the archdeaconry of St Asaph. In educational matters, the Latin or second-grade schools comprise the endowed grammar schools of Holt, founded in 1661; Denbigh, in 1726; Wrexham, in 1603; Rhuabon, by Vicar Robinson, in 1703; and Llanrwst, by Sir John Wynne of Gwydir, in 1610. The Greek, or highest grade, is supplied by that of Ruthin, founded in 1574 by Dr Gabriel Goodman, dean of Westminster, a native of the town and the refounder of its Christ's Hospital. This school has been the nursery of many eminent Welshmen.

Antiquities.—Of prehistoric remains, the caves in the limestone escarpments of Cefn, that overhang the valley of the Elwy, yield a noteworthy supply. They contain remains of the hippopotamus, elephant, rhinoceros, lion, hyena, bear, reindeer, &c. The glutton was found in the neighbouring cave of Plas Heaton, flint implements in the adjoining Bont Newydd cave, and a polished stone-axe in a similar one at Rhosdigre,—all in the same range. Near Cefn, too, was discovered in 1869, on the opening of a carnedd in Tyddyn Bleiddya, a

chambered tomb containing skeletons, which, on comparison with a similar type found at Perth Chwareu, gave rise to the title of the "Platycnemid Men of Denbighshire."

A writer in the *Archæologia Cambrensis*, 1855, p. 270, has given a summary of the antiquities of the county, most of which may be put down as British or at least Celtic. Traces of the Romans exist at Clawdd Coch (Mediolanum?), Penygner, Bwlch, Penbarras, and their roads passed from Deva (Chester) to Segontium (Carnarvon) and to Mons Herri (Tomen-y-Mur) respectively. To the Romano-British period belong the inscribed stones at Gwytherin and Pentrefoelas. The Pillar of "Ehseg," near Valle Crucis, tells of Brochmael and the struggle against the invading Northumbrians under Ethelfrith, 613 A.D., whilst the Dyke of "Offa" hands down the memory of the Mercian advance. Adjoining this last, and running side by side with it, is the similar but shorter earthwork called "Watt's Dyke," of debateable origin and purpose.

Of the earliest castles the ruins of "Dinas Bran" still crown the conical hill that overhangs Llangollen. Denbigh, which has been compared to Stirling for site and beauty—built in the time of Edward I. and destroyed in the civil wars—overlooks the Vale of Clwyd; Holt, on the banks of the Dee, probably the Caerlegion of Beda, shared the same fate. Ruthin, overthrown at the same time, has been twice rebuilt within this century. Chirk alone has weathered the storms of time and war, and is still occupied as a family residence.

Among the early ecclesiastical buildings and remains we may name the Cistercian abbey of Valle Crucis and the Carmelite chapel at Denbigh, both now in decay, the cloisters at Ruthin, and the old house of Brynffynnon, sometimes called the nunnery at Wrexham, the collegiate churches of Wrexham and Ruthin; the beautiful rood-lofts and screens of Llanrwst, Gresford, and Derwen, the portrait brasses and monuments in the Gwydir Chapel, Llanrwst, and at Whitechurch, Denbigh; the churchyard cross at Derwen; and the stained glass at Gresford and Llanrhaidr in Dyffryn Clwyd.

The principal gentlemen's seats of Tudor date comprise Gwydir (Lady Willoughby d'Eresby), Brynkmallt (Lord A. E. Hill-Trevor), Trefalyn (B. T. Boscawen Griffith), Llwyn Ynn (Colonel Heygarth), Cadwgan (in decay). Those of later erection include Llangedwyn and Wynnstay (Sir W. Williams Wynn, Bart.), Kinnel (H. R. Hughes), Pool Park (Lord Bagot), Havodunos (H. R. Sandbach), Voelas (Colonel Wynne Finch), Llanerch (Whitehall Dod), Gwrych Castle (R. B. Hesketh), Plas Power (T. Fitzhugh), Llandysilio Hall (C. F. Beyer), Acton Park (Sir R. H. Cunliffe, Bart.), Galltfaenan (T. Mainwaring), Erviatt (J. J. Foulkes), Glanywern (P. S. Humberston), Gelligynan (J. Carstairs Jones).

Among the books bearing upon the history of the county are the following—the *Archæologia Cambrensis*, or Journal of the Cambrian Archaeological Association, Pennant's *Tours in Wales*, Lewis, *Topographical Dictionary*; Thomas, *History of the Diocese of St Asaph*, *Annals of Counties and County Families of Wales*, by Dr Nicholas, *Yorke's Royal Tribes of Wales*, *Memoirs of the Gwydir Family*, by Sir John Wynne; *Memoirs of the Goodmans*, by R. Newcome, *Accounts of Denbigh and of Ruthin*, by the same, *Ancient and Modern Denbigh*, by John Williams, *Records of the Lordship of Denbigh*, by the same, *Handbook of the Vale of Clwyd*, by Davies; *Wrexham and its Neighbourhood*, by Jones. The village churches of the county have been well illustrated by Lloyd Williams and Underwood, architects, of Denbigh. (D. R. T.)

DENDERAH, an Arab village in Upper Egypt, about 28 miles north of Thebes, marking the site and preserving the name of the ancient city of Tentyra, which was the capital of the Tentyrite nome and the seat of a famous temple dedicated to Athor, the Egyptian Venus. The temple, which is remarkable as the first well-preserved and

unencumbered building of the kind to be seen on a voyage up the Nile, lies about a mile and a half from the left bank of the river, within a square inclosure formed by four crude-brick walls, each 1000 feet in length, and entered by means of a stone-built gateway, adorned with sculptures representing Domitian and Trajan engaged in acts of worship. The portico of the temple is about 135 feet in width, and is architecturally one of the richest and most beautiful structures of its class. It is supported by 24 columns, four deep, nearly 50 feet in height, and having a diameter of more than 7 feet at the thickest part. The capitals have sculptured on each of their four sides a full face of Athor, crowned by a small shrine or temple. The sculptures, which are of less merit than the architecture, represent offerings made by some of the earlier Cæsars, and on the ceiling are various mystical subjects, probably of an astronomical import, and the famous quadrangular zodiac, which will be referred to again in the latter part of this article. Passing through the back wall of the portico (which was at one time the front wall of the temple) the visitor enters a hall supported by three columns on each side, with cup-shaped capitals beneath those formed by the temple-crowned faces of Athor; and thence, proceeding right onwards through two similar halls, he reaches the sanctuary, which is isolated by a passage running all round. On each side of the temple are many small apartments, and two entrance-ways from the exterior, as well as singular inclined passages in the walls, two of which are entered from the sides of the portico. All the chambers and passages, except the two last mentioned, are profusely covered with sculptures and inscriptions of a religious character, chiefly depicting and narrating the piety of the sovereigns by whom the temple was erected. The royal names have not always been filled in, but, where they have been sculptured, they are generally those of the last Cleopatra, and Cæsarion, her son by Julius Cæsar. A staircase on the left-hand side of the second chamber, behind the portico, conducts to the roof of the temple. Here are a sort of chapel and some small chambers, one of which is very interesting, because its sculptures relate to the story of Osiris. The exterior of the temple is as completely covered with sculptures as the interior. Among the figures represented there are those of Cleopatra and Cæsarion; but they cannot be supposed to bear any resemblance, since they belong not alone to a conventional art, but almost to its lowest period. There are two smaller temples within the same inclosure as the great temple of Athor, one dedicated to Isis in the thirty-first year of Augustus, and the other usually known as the *Typhonium*, from the representations of Typhon on the capitals of its columns, but probably connected with the worship of Athor.

The name Denderah, in Coptic *Tentore*, and in Greek *Tenty*, a or *Tentyris*, used to be regarded as equivalent to *Thyn Athor*, "the abode of Athor;" but, according to an hypothesis started by Brugsch, and since proved by the investigations of Dumichen, it is now explained as "the Land of the Hippopotamus" (*Tan-ta-rer*), in allusion to the use of this animal as a symbol of the goddess Isis, who is regularly identified with Athor in the Denderah inscriptions. The sacred name was An, and a list is still extant of 136 substitutes or *epitheta ornantia*, such as the house of enlightened souls, the house of gladness, the house of the weeping and laughing of the sun-god Ra. Though, as already indicated, the present temples of Denderah belong to the latest period of Egyptian art, the original occupation of the site for sacred buildings dates from the earliest times. According to an inscription discovered and published by Dumichen, who spent three months in personal exploration of the ruins, a restoration of the temple was effected

by Thothmes III. of the 18th dynasty, in keeping with an ancient plan belonging to the reign of Chufu, which had been found, in the time of Pheops, "in the interior of a wall of the Southern House."

The people of Tentyra were remarkable for their hostility to the crocodile and its worshippers; and in their attacks on the reptile they displayed so much audacity and skill that the Romans in the time of Strabo brought a number of them over to Italy as a new attraction for the amphitheatre. In modern times the name of Denderah has become especially famous on account of the two designs known respectively as the circular and the quadrangular zodiac, which have been the subject of the most elaborate discussion among Egyptologists. The former was discovered by General Desaix about the end of last century, and at length in 1820 removed by M. Belorain to Paris, where it was purchased by the Government for 150,000 francs, and deposited in the *Bibliothèque Impériale*; the latter, first observed by M. Dupuis, a member of the French commission, is still in its original position, as, instead of occupying a comparatively small and portable disk, it forms, as already indicated, the decoration of two extremities of the temple portico, and thus consists of two corresponding halves. Copies of both the zodiacs have frequently been made, and are easily accessible in F. C. Lauth's *Les Zodiacs de Denderah*, Munich, 1865, a memoir in which he maintains that both designs are commemorative calendars of the Greco-Roman period.

See also Wilkinson's *Ancient Egyptians*; Le Roux, *Observations sur l'objet des représentations zodiacales de l'antiquité*, Paris, 1821; Halm, *Examen et explication des Zodiacs Égyptiens*, 1822; Lepsius's *Zeitschrift für Ägyptische Sprache und Alterthumskunde*, *passim*; Chabas, *Sur l'antiquité de Denderah*, and especially Dumichen's *Neueste Mittheilungen aus Ägypten, und Bauwerke der Tempelanlagen von Denderah*, 1864.

DENDERMONDE, in French *Termonde*, a town of Belgium, in the province of East Flanders, about 18 miles east of Ghent, so called from its situation at the mouth of the Dender, a right-hand affluent of the Scheldt. It is the seat of a court of primary instance, has a hospital, a lunatic asylum, two orphanages, an academy of architecture and design, a public library, and a picture gallery, and carries on the manufacture of woollens, linens, ropes, paper, tobacco, and various other branches of industry. In the old church of Notre Dame, which was raised to collegiate rank in 1106, there are two paintings by Vandijk—a Crucifixion and an Adoration of the Shepherds. Till 1264, when it passed into the possession of Robert Bethune, count of Flanders, Dendermonde was governed in direct dependence on the empire. Its name frequently occurs in the history of the various wars in the Low Countries, the most memorable occasions being in 1667, when it defended itself against Louis XIV. by laying the neighbourhood under water; in 1706, when it was besieged and captured by General Churehill, and in 1745, when it was taken by the French. The fortifications were dismantled by Joseph II in 1784; but they were restored in 1822. The bridge over the Scheldt dates from 1825. Population in 1866, 8300.

DENHAM, SIR JOHN (1615–1668), a royalist poet, who has won a place among the foremost British authors more by a happy accident than by any decided genius, was the only son of Sir John Denham, lord chief baron of the Exchequer in Ireland, and was born in Dublin in 1615. In 1617 his father was promoted to the rank of baron of the Exchequer in England, and removed to London with his family. The future poet attended a grammar school in London, and in Michaelmas term 1631 was removed to Oxford, where he was entered a gentleman commoner of Trinity College. Having taken his degree of B.A., he began the study of the law at Lincoln's Inn in 1634; but the character he had

maintained at Oxford, of being "a slow, dreaming young man," gave way to a scandalous reputation for gambling, by which he beggared himself and seriously embarrassed his father. We learn that, by way of penance, he wrote at this time an *Essay against Gaming*, whether in prose or verse is not recorded. After his father's death the habit became still more dominant, and he squandered a fortune. It was a surprise to every one, therefore, when in 1642 he suddenly, as Waller said, "broke out like the Irish rebellion, threescore thousand strong, when no one was aware, nor in the least expected it," by publishing in that year two most successful volumes of verse. The first of these was *The Sophy*, a tragedy in five acts, a thin folio, the theme of which was a Turkish tale of blood and intrigue, drawn from Sir Thomas Herbert's travels. This, Denham's only dramatic performance, is tame and correct, without passion, but free from the faults of some of the minor authors of the time. It was successful, but it enjoyed nothing of the unparalleled popularity of his simultaneous venture, the descriptive poem of *Cooper's Hill*, the first edition of which in quarto was anonymous. In this famous piece no entirely new style was attempted, for Ben Jonson had led the way in theme and Cowley in manner; but it had a smooth grace and a polished antithesis that were doubtful merits in poetry, but extremely dear to the rising generation. One quatrain, out of the three or four hundred lines of reflection and description, has been universally praised, and forms one of our most familiar quotations. Addressing the Thames, the poet says—

"O could I flow like thee, and make thy stream
My great example, as it is my theme!
Though deep, yet clear; though gentle, yet not dull;
Strong without rage, without o'erflowing full."

Brought into royal notice by his poems, Denham was appointed high sheriff for Surrey and governor of Farnham Castle; but he showed no military talent, and soon followed the king to Oxford. During the civil war he served the queen mother, and was intrusted with the letters in cipher that Cowley wrote to the king, which he managed to deliver into Charles's hands. Being detected, however, he was obliged to escape into France. In April 1648 he is said to have conveyed the young duke of York from St James's to Paris; it is certain that, later in that year, he was sent in company with Lord Crofts, as ambassador to Poland, to obtain money for the king, and he succeeded in bringing back £10,000. In 1652 he returned, a ruined man, to England, and resided as the guest of the earl of Pembroke at Wilton for a year. He now disappears until the Restoration. When Charles II. returned, Denham was made surveyor-general and Knight of the Bath, and seems to have been well provided for; but his subsequent life was far from happy, for his second wife, a young woman of great beauty, was seduced by the duke of York, and became his mistress. This catastrophe, which is abundantly noticed in the current literature of that day, shattered the old poet's reason; and he recovered from his insanity only to die, at his house near Whitehall, on the 10th of March 1668. He was buried in Westminster Abbey. In the same year, 1668, his works were collected in a single volume, entitled *Poems and Translations*. This included, besides *Cooper's Hill* and *The Sophy*, a fragment of an epic on the destruction of Troy, some beautiful lines on the death of Cowley, written a few months before his own decease, a didactic poem on the progress of learning, and some translations. Notwithstanding the fame of *Cooper's Hill*, which Pope imitated in his *Windsor Forest*, Denham's poems have not been edited in modern times. He was one of the very first to note the tendency towards rhetorical and gallicized forms in public taste, and to gratify the new fashion. But to speak of him, as

was once customary, as a great reformer of metre and fashioner of language, is to fail to realize the limitations of his talent.

DENINA, CARLO GIOVANNI MARIA (1731–1813), an Italian author, was born at Revello, Piedmont, in 1731, and was educated at Saluzzo and Turin. In 1753 he was appointed to the chair of humanity at Pignerol, but he was soon compelled by the influence of the Jesuits to retire from it. In 1756 he graduated as doctor in theology, and began authorship with a theological treatise. Promoted to the professorship of humanity and rhetoric in the college of Turin, he showed his literary activity in his great work *On the Revolutions of Italy*, and in other writings. Collegiate honours accompanied the issue of its successive volumes, which, however, at the same time, multiplied his foes and stimulated their hatred. In 1782 he repaired to Berlin, where he remained for many years, in the course of which he published various works. In 1804 he went to Paris as the imperial librarian, to which office he had been appointed by Napoleon, who was attracted to him at Metz. He died there on 5th December 1813. Denina's reputation is mainly founded on his *History of the Revolutions of Italy*, in which he combines a philosophic spirit and the habit of accurate narration.

DENIS, or DIONYSIUS, St, the patron saint of France, flourished in the middle of the 3d century. What is known of his life rests chiefly on the not altogether trustworthy authority of Gregory of Tours, according to which he was the leader of a band of seven missionaries who came from Rome to Gaul, and founded churches in seven cities. Denis settled in Paris, where he made many converts, and became the first Christian bishop. In 272, during the persecution of Valerian, he was beheaded along with some of his companions. Another account places the date of the martyrdom between 286 and 290. The well-known legend, according to which St Denis after his decapitation walked two miles with his head in his hands, probably originated in a mistaken interpretation of pictures intended to indicate the manner of his death. It was not unusual to represent a martyr by decapitation bearing his head in his hands as an offering, and there are effigies of St Denis with the mitred head in its natural position and the head in the hands as well. The bodies of the three martyrs were thrown into the River Seine, but were afterwards recovered and honourably buried by a Christian lady named Catalla, not far from the place where they suffered. Over the tomb a chapel was built, which in the 5th century was replaced by a church. The famous abbey of St Denis was founded on the same spot by Dagobert in the 7th century. A later legend of the French church, following the tradition of the Greek Church, identified St Denis of Paris with Dionysius the Areopagite, who was converted by St Paul. One of the gravest charges brought against Abelard was the fact that he denied this identity on the authority of a passage in Bede. St Denis was gradually adopted as the patron saint of the French people, St Louis being the patron saint of the royal family. His festival is celebrated on the 9th October.

DENIZEN, an alien who obtains by letters patent (*ex donatione regis*) certain of the privileges of a British subject. He cannot be a member of the Privy Council or of Parliament, or hold any civil or military office of trust, or take a grant of land from the Crown. The Naturalization Act, 1870, provides that nothing therein contained shall affect the grant of any letters of denization by Her Majesty. See NATURALIZATION.

DENMAN, THOMAS, FIRST BARON (1779–1854), one of the most distinguished of the chief-justices of England, was born at London, the son of a well-known physician, 23d July 1779. He received the rudiments of his educa-

tion at Palgrave School, near Diss, in Norfolk, at that time conducted by Mrs Barbauld. At ten years of age he was sent to Eton, and he afterwards was entered at St John's College, Cambridge, where he graduated in 1800. He took only an ordinary degree, having a positive distaste for mathematics. Soon after leaving Cambridge he married; and in 1806 he was called to the bar at Lincoln's Inn, and at once entered upon practice. His success was rapid, and in a few years he attained a position at the bar second only to that of Brougham and Scarlett. He distinguished himself by his eloquent defence of the Luddites; but his most brilliant appearance was as one of the counsel for Queen Caroline. His speech before the Lords was very powerful, and some competent judges even considered it not inferior to Brougham's. It contained one or two daring passages, which made the king his bitter enemy, and retarded his legal promotion. At the general election of 1818 he was returned M.P. for Wareham, and at once took his seat with the Whig opposition. In the following year he was returned for Nottingham, for which place he continued to sit till his elevation to the bench in 1832. His liberal principles had caused his exclusion from office till in 1822 he was appointed common serjeant by the corporation of London. In 1830 he was made attorney-general under Lord Grey's administration. Two years later he was made lord chief-justice of the King's Bench, and in 1834 he was raised to the peerage. As a judge he is most celebrated for his decision in the important privilege case of Stockdale v. Hansard, but he was never ranked as a profound lawyer. In 1850 he resigned the chief-justiceship of the Queen's Bench and retired into private life. He died September 26, 1854.

See *Memoir of Thomas, first Lord Denman*, by Sir Joseph Arnould, 2 vols. 1873

Plate I.

DENMARK. The kingdom of Denmark, once a considerable power in Europe, but now confined within very narrow limits, comprises the peninsula of Jutland on the European continent and a group of islands in the Baltic. It lies between $54^{\circ} 34'$ and $57^{\circ} 44' 52''$ N. lat., and between $8^{\circ} 4'$ and $12^{\circ} 34'$ E. long, with the exception of the Island of Bornholm, which lies between $14^{\circ} 42'$ and $15^{\circ} 10'$ E. long. It is bounded N by the Skagerrack; E by the Cattagat, the Sound, and the Baltic; S. by the Baltic, the Little Belt, and the German duchy of Schleswig; and W. by the North Sea. Its area amounts to 14,553 English square miles. With the exception of Bornholm, which is situated considerably to the east between Pomerania and Sweden, the islands all lie close to one another, and form a cluster that almost closes the entrance to the Baltic. The largest island, and the nearest to Sweden, is Zealand, or Sjælland; the next in size, Funen, or Fyn, is divided from Jutland by only a minute channel; Lolland, Bornholm, Falster, Langeland, Moen, Samso, Ærø, Læsø, Thasinge, Anholt, are, in order of their importance, the other noticeable islands.

Coast and Surface.—The coasts of Denmark is generally low and sandy; the whole western shore of Jutland is a succession of sand-ridges and shallow lagoons, very dangerous to shipping. Skagerrack, or the Scaw, a long, low, sandy point, stretches far into the northern sea, dividing the Skagerrack from the Cattagat. On the eastern side the Skagerrack is not so inhospitable; on the contrary there are several excellent havens, especially on the islands. Nowhere, however, is the coast very high, except at one or two points where limestone cliffs exist. The long fjords, or Moen, except to which the proximity of the islands divides the fjords, is a distinguishing feature. There is little variety in the surface of Denmark. It is uniformly low, the highest point in the whole country, Himmelbjerget in

Jutland, being only 550 feet above the sea. Denmark, however, is nowhere low in the sense in which Holland is; the country is pleasantly diversified, and rises a little at the coast even though it remains flat inland. The landscape of the islands and the south-eastern part of Jutland is rich in beech-woods, corn-fields, and meadows, and even the minute islets are green and fertile. In the western and northern districts of Jutland this gives place to a wide expanse of moorland, covered with heather, and ending at the sea in low, whitish-grey cliffs. There is a melancholy charm even about these monotonous tracts, and it cannot be said that Denmark is wanting in natural beauty, though of a quiet order. It is obvious that in such a country there can exist no rivers. The Gudena, the longest of the Danish streams, is little more than a brook. Nor are there any large lakes. Pieces of water of considerable size, however, are numerous; of these the largest are the Arresø and the Esromsø in Zealand, and the chain of lakes of various names near Silkeborg in Jutland. Many of these mores, overhung with thick beech-woods, are extremely beautiful.

The climate presents no remarkable features. The country lies at the division between Eastern and Western Europe, and partakes of the characteristics of both. Its climate differs from that of Scotland (which is in the same latitude) less in the nature of the seasons than in the rapidity of their transitions. The following are the mean annual temperature (Fahr.):—

	Copenhagen.	Frederikshavn.
Winter	32.9	32.
Spring	43.7	43.02
Summer	63.05	60.65
Autumn	49.1	48.65
Whole year	47.18	46.00

Snow falls on an average on thirty days in the year, and westerly winds are more prevalent than easterly in the ratio of 16 to 10. Storms of wind and rain are exceedingly frequent, particularly in July and August. In the district of Aalborg, in the north of Jutland, a cold and dry N.W. wind called *skai* prevails in May and June, and is exceedingly destructive to vegetation; while along the west coast of the peninsula similar effects are produced by a salt mist, which carries its influence from 15 to 30 miles inland.

The fauna of Denmark presents no peculiarity. The wild animals and birds are those of the rest of Central Europe. The larger quadrupeds are all extinct; even the red deer—which was formerly so abundant that in a single hunt in Jutland in August 1593 no less than 1600 head of deer were killed—is now only to be met with in preserves. In the kjokken-møddings and elsewhere, however, are found vestiges which prove that the urochs, the wild boar, the beaver, the bear, and the wolf have all existed since the arrival of man. The usual domestic animals are abundantly found in the Denmark of to-day, with the exception of the goat, which is very uncommon.

In her flora, Denmark presents greater variety than would have been anticipated from so low and monotonous a country. The ordinary forms of the north of Europe grow with great luxuriance in the mild air and protected soil of the islands and the eastern coast, while on the heaths and along the sandhills on the Atlantic side there flourish a great variety of unusual species.

The Danish forest is almost exclusively made up of beech, a tree which thrives better in Denmark than in any other country of Europe. The oak and ash are now rare, though in ancient times both took a prominent place in clothing the Danish islands. The almost universal predominance of the beech dates from about two centuries ago. In the reign of Christian IV. the oak was still the characteristic Danish tree. No conifer grows in Denmark, except under careful

cultivation. In Bornholm, it should be mentioned, the flora is more like that of Sweden; not the beech, but the pine, birch, and ash are the most abundant trees.

Agriculture.—Denmark is pre-eminently a corn land, and the cereals grown are all the usual European varieties; in the light and sandy soils buckwheat takes the place of rye, wheat, barley, and oats. The potato is largely cultivated, as well as pease, clover, vetches, and turnips. The usual North European fruit-trees and bushes produce good crops, and even peaches and apricots ripen well in sheltered places. The nectarine, however, is not known as a hardy fruit. The produce of grass is not very large, the fertility of the ground tempting the farmers to use it all for grain. In relation to its size there is no country in Europe, except Belgium and England, that can compete with Denmark as a corn-producer. According to the official returns of 1871, there were in that year 11,367,310 acres under some sort of crop, fallow, or in grass, or about 65 per cent. of the total area of the country; 5,894,495 acres more were in woods and forests. The following table will show the distribution of the crops, in English statute acres:—

Wheat	128,558	Carrots, turnips, }	12,753
Barley	689,734	cabbage, &c. }	
Oats	840,435	Rape and other oil }	3,037
Rye	561,607	seeds	
Beans and pease ..	80,366	Flax and hemp ..	17,686
Buckwheat	45,180	Bare fallow	538,354
Mixed corn	122,606	Grass under rotation	307,460
Potatoes	97,317	Permanent pasture	2,433,356

Of the actual production of the above crops no estimate has been furnished by the Statistical Bureau. The land in Denmark is minutely subdivided, owing partly to the state of the law, which interdicts the union of small farms, and encourages in various ways the parcelling out of landed property.

The large estates of the nobles are generally in the hands of farmers; but the greater part of the land is possessed by the peasantry, who maintain an hereditary attachment to their ancestral farms. Below these are the small peasant estates (generally capable of supporting from 10 to 15 cows), there is also a class of cottar freeholders called *junsters*, with land sufficient to keep one or two cows. The most remarkable feature in the Danish husbandry is, that greater value is attached to the produce of the dairy than to that of the soil, and that much of the horse power is withdrawn from the fields and employed in the work of the dairy. Independently of the stock maintained in the large dairy farms, this branch of industry has given rise to a distinct class of men, hiring cows by the year. Notwithstanding the great extent of pasture, the country produces more grain than is required for its own consumption.

The mineral products of Denmark are too unimportant to require enumeration. It is one of the poorest countries of Europe in this particular. It is rich, however, in clays, while it should be stated that in the island of Bornholm there are quarries of freestone and marble. There is but little coal yet discovered in the country.

Manufactures are not carried on to any great extent. The most notable Danish manufacture is the fabrication of porcelain. The nucleus of this important industry was a factory started in 1772, by F. H. Müller, for the making of china out of Bornholm clay. In 1779 it passed into the hands of the state, and has remained there ever since. Originally the Copenhagen potters imitated the Dresden china made at Meissen, but they are now famous for very graceful designs of their own invention, and their porcelain has a distinct character of its own. The inventions of Thorwaldsen have been very largely repeated and imitated in this charming ware. Besides the royal works,

there are private factories employing a large number of men. Terra cotta and faience are also manufactured in Copenhagen. The iron-works of Denmark have made very considerable progress since the separation of Norway, and they are largely supplied with raw material imported from England. There are many iron foundries around Copenhagen, and in that city there are small manufactories of locomotives, and of machinery of various kinds.

The woollen, linen, and cotton manufactures of Denmark are for the most part domestic, and carried on purely for local consumption. Linen is the principal article of domestic industry in Zealand. The woollen manufacture occupies about 2000 men. The sugar refineries, of which the largest are at Copenhagen, prepare most of the sugar required for domestic consumption. Cherry brandy is also prepared in that city, and largely exported. The making of paper and distillation are carried on at different parts of the country to some extent.

Commerce.—Formerly the commercial legislation of Denmark was to such a degree restrictive that imported manufactures had to be delivered to the customs, where they were sold by public auction, the proceeds of which the importer received from the custom-houses after a deduction was made for the duty. To this restriction, as regards foreign intercourse, was added a no less injurious system of inland duties impeding the commerce of the different provinces with each other. The want of roads also, and many other disadvantages, tended to keep down the development of both commerce and industry. Within the present century, however, several commercial treaties were concluded between Denmark and the other powers of Europe, which made the Danish tariff more regular and liberal.

Of no less importance were the regulations made from time to time concerning the Sound toll, a question which in the 17th century led to many hostilities between Denmark, Sweden, and Holland. Having formerly possessed both sides of the entrance to the Baltic, the Danish Crown looked upon the Sound as exclusively her own, refusing to admit any foreign vessels without payment of a certain duty, and this right was never successfully contested by the other powers. An exception, however, was made in favour of Sweden, and of late the toll has been entirely abolished.

The principal ports of Denmark are Copenhagen, Helsingør, Korsør, Aarhus, Aalborg, and Frederikshavn.

The total value of the goods imported into Denmark in 1874 was £12,859,000; and of the goods exported, £9,574,000.

The following tables show the quantities of the principal articles imported and exported in the same year. We give them in the original figures, premising that a *tonde* of corn equals 3·8 imperial bushels, a *tonde* of coal 4·6775 bushels, and a *pund* 1·102 lb avoirdupois.

IMPORTS	
Chicory	3,561,354 pund
Coals	3,610,035 tonder.
Coffee	23,668,775 pund
Corn—oats	32,274 tonder.
" rye	218,537 "
" wheat	134,141 "
Glass wares	4,605,533 pund.
Hides and skins, raw ..	5,837,858 "
Cotton manufactures ..	11,468,192 "
Woollen	3,672,834 "
Metals, iron wrought and unwrought	96,938,041 "
" ore	23,320,340 "
Oil, of all kinds	15,112,611 "
Rice	17,690,787 "
Salt	40,877,099 "
Sugar	54,353,700 "
Tea	772,396 "
Tobacco	5,955,629 "

EXPORTS.

Oxen and Cows	66,986 head.
Swine	175,921 "
Bones, whole or ground.	3,759,509 pund
Butter	23,144,128 "
Corn—barley	1,001,969 tonder
" barley meal	6,308,424 pund.
" oats	575,408 tonder.

" tongues, sausages	2,338,814 "
Oilcake	7,258,413 "
Rags	3,546,365 "
Wool	3,515,101 "

The decimal system of coinage is in use in Denmark, the unit being the ore, $7\frac{1}{2}$ of which are equivalent to an English penny, 100 ore make 1 krone, equal to about 1s $1\frac{1}{4}$ d. sterling.

Government.—In early times the government of Denmark was far from despotic; the succession to the Crown was even elective until the revolution of 1660. It then became entirely without constitutional check upon the will of the king. This singular change is to be explained by supposing, on the part of the nation, not so much an indifference to free institutions as a resentment of the overbearing conduct of the nobility, and a consciousness of the perpetual uncertainties of an elective Government. The court found it thus a matter of little difficulty to unite the clergy and commons against the aristocracy; and the power of the Crown has since continued without a parliament or any constitutional check. But when Frederick VII. came to the throne he promised to resign the nearly absolute power which had hitherto been connected with the Crown. Accordingly a charter was drawn up by an assembly elected for that purpose in 1849, and signed by the king in 1850, which acknowledged the principle of limited monarchy, the king sharing his power with a diet of two houses, both of which are elective. The first, called Folksting, has the privilege of discussing the budget and other public questions, while the other is confined to the local affairs of the provinces. The liberty of religion and of the press, and the inviolability of person and property, were amply guaranteed by the new constitution. This great charter received a further revision on the 28th of July 1866, according to which the second chamber, called the Landsting, consists of 66 members, 12 of whom are nominated for life by the king, and the others elected for 8 years—7 by the city of Copenhagen, 45 by the electoral districts of the towns and country, 1 by Bornholm, and 1 by the Faroe Islands. The Folksting is composed of one representative for every 16,000 inhabitants, elected for three years. In 1875 it contained 102 members. The privy council consists of the king, the crown prince, and the ministers.

The financial state of the kingdom will best appear from the following net estimates contained in the budget for 1876–77, given in kroner (1s $1\frac{1}{4}$ d. sterling):—

RECEIPTS.

Domains	937,450
Forests	796,872
State surplus	4,834,494
Direct duties	8,385,050
Indirect duties	29,297,000
Posts	379,941
Telegraphs	20,980
Lotteries	850,000
Receipts from the Faroes	38,513
" from the West Indies	25,000
Various receipts	1,187,772
Drawback, &c	1,331,880

(£2,671,441) 48,085,952 kroner.

EXPENDITURE.

Civil list	1,000,000
Royal apauage	442,544

Public works	3,718,550
Subventions, &c	780,726

(£2,594,170) 46,695,071 kroner.

The national debt amounted in 1875 to 100,805,939 kr. (£5,600,330)

Army and Navy.—The army is regulated according to the principles fixed by the law of the 6th of July 1867. Conscription is practised. The service begins at the age of twenty-two years, and continues eight years for the line and the reserve (first grade); the second grade goes on to the age of thirty-eight years. The following table shows the condition of the Danish army according to the latest statistics:—

	Regular Army		Army of Reserve	
	Officers.	Rank and File	Officers	Rank and File.
Infantry	730	26,750	287	12,127
Cavalry	126	2,122		
Artillery	139	6,523	37	2,391
Engineers	36	580	22	740
Total	1031	35,975	346	15,258

The staff of the army was composed, at the same time, of 25 commissioned and 37 non-commissioned officers. The navy of Denmark comprised, at the commencement of September 1875, 6 iron-clads, 12 unarmoured vessels, 7 gun-boats, and 5 paddle steamers,—the whole carrying a total of 286 guns. The navy is recruited by conscription from the coast population. It was manned in September 1875 by 911 men, and officered by 1 admiral, 15 commanders, and 81 captains and lieutenants. In March 1875 the mercantile fleet of Denmark comprised 2846 vessels, of an aggregate burden of 212,600 tons.

The fortifications of Copenhagen have within the last few years been entirely razed, but the city is still protected by some forts in the Sound. The castle of Kronborg, near Helsingör, interesting to Englishmen as the scene of *Hamlet*, is in good preservation, and well-manned. The port of Frederikshavn, in the extreme north of Jutland, is also strongly fortified.

Religion and Education.—The established religion of Denmark is the Lutheran, which was introduced as early as 1536, the church revenue being at that time seized and retained by the Crown. In no country of Europe was the Reformation introduced in a more bloodless and easy way than in Denmark. During the earliest Christian times the whole of Denmark was under the jurisdiction of the archbishop of Hamburg. King Erik Eiegod, after a personal visit to the Pope, contrived to place his kingdom under a Scandinavian prelate and his own subject, the archbishop of Lund in Skania, which then belonged to the Danish dominions. After the cession of Skania to Sweden, Roeskilde became the metropolitan see. At present (1877) there are six bishops, besides the metropolitan, viz, the bishops of Funen, of Lolland and Falster, of Aarhus, of

Aalborg, of Viborg, and of Ribe. They have no political function by reason of their office, although they may, and often do, take a prominent part in politics. Dissent is comparatively unknown, or at least it has not yet become a serious danger to the national church. The Mormon apostles for a considerable time made a special raid upon the Danish peasantry, but the emigration to Great Salt Lake City is now but small. Roman Catholics were until lately hardly existent in Scandinavia, where their presence was not tolerated. The following statistics will show the proportion of religious bodies at the census of 1870:—Lutherans, 1,770,000, Jews, 4300; Baptists, 3200; Mormons, 2200; Roman Catholics, 1800, Irvingites, 350. Complete toleration is now enjoyed in Denmark.

The educational institutions of Denmark have reached a very high degree of perfection; indeed few countries, if any, can compete with Denmark in this respect. Most of the peculiar advantages in the Danish system seem to arise from this, that all schools, both grammar and other, have been put in a state of dependence on the university of Copenhagen, and under its control, while the university itself is particularly well managed. All educational institutions of the country are now managed by a royal college, consisting of three or four assessors and a president, called the royal commission for the university and grammar schools. This commission has no superior but the king, and reports to him directly. It appoints all professors in the university of Copenhagen, all rectors, co-rectors, and other teachers of grammar schools, and also promotes these functionaries from lower to higher grades. Education is compulsory. Poor parents pay a nominal sum weekly for the education of their children at the Government schools, so that almost all the lower class can read and write. Confirmation is also compulsory, and till that rite has been received, the youth of both sexes are in *statu pupillari*. Certificates of baptism, confirmation, and vaccination are indispensable before entering on service, apprenticeship, or matrimony.

Territorial divisions.—These consist of provinces, amts, and parishes. The provinces are seven, and correspond to the episcopal sees above mentioned. Of these provinces three are in the islands.—Zealand, which includes Bornholm and Moen; Lolland and Falster, comprising those two islands; and Funen, which also includes Langeland, Æro, and Taasinge. Four provinces are on the mainland.—Aarhus, occupying the south-east of Jutland; Aalborg, the north, Viborg, the centre; and Ribe, the south-west of the same. Each of these provinces is divided into several amts, answering very much to the English hundreds.

The only large city in Denmark is Copenhagen in Zealand, which was estimated in February 1876 to have a population of 199,000, and, with its-suburbs, of 233,000. Thirteen other towns contain 5000 inhabitants, and upwards—viz., Odense (Funen), 17,000; Aarhus (Jutland), 15,000; Randers and Aalborg (Jutland), 12,000 each; Horsens (Jutland), 11,000; Helsingør (Zealand), 9000; Fredericia (Jutland), 7000; Viborg (Jutland), Svendborg (Funen), and Vejle (Jutland), 6000 each; Ronne (Bornholm), Slagelse (Zealand), Kolding (Jutland), and Roeskilde (Zealand), 5000 each.

Communication both by land and water is well provided for in Denmark. A railway from the Schleswig frontier proceeds to Fredericia, from whence one branch passes to the extreme north of Jutland, another crosses the island of Funen from Middelfart to Nyborg. This is the direct route from Germany to Copenhagen. From Nyborg a packet crosses the Great Belt to Korsør, and thence another line runs through Zealand to Copenhagen. There is also a south Zealand line, from Roeskilde to Vordingborg, which is continued through the island of Falster, besides

a short line in Lolland. The only canal is the Thyborøn, a short canal which connects the Lum Fjord (the arm of the sea which penetrates so far into the north of Jutland) with the German Ocean. This is a natural canal, formed after the Agger channel (a passage opened by the storm of the 3d of February 1825) had become choked with sand. The canal can only be used by vessels of very small burden.

Dependencies.—The colonial possessions of Denmark are the Faroe Islands, Iceland, Greenland, and the Danish West Indies. The Faroe Islands are an archipelago nearly midway between Shetland and Iceland. They are considered as an out-lying amt of the mother-country rather than as a colony. Seventeen of these islands are inhabited; the largest is Stromo, on the eastern shore of which is built the capital Thorshavn. The islands are governed by an amtmand.

Iceland is a large island at the north-western extremity of the map of Europe, just outside the Arctic Circle. Until lately it was considered as a colony of Denmark, and was subject to a tyrannous exercise of the laws of the mother country on the part of small officials. At the visit of Christian IX, however, in 1874, it received a constitution and an independent administration, which came into force in August of that year.

The possessions of Denmark in the West Indies consist of three islands lying to the east of Porto Rico. Of these St Croix is the largest, and St John the smallest, while the chief town and the residence of the governor are on St Thomas. A few years ago the last named island was offered to and very nearly purchased by the United States, but the proceedings fell through.

The whole peninsula or continent of Greenland is nominally in the possession of Denmark; but in point of fact her dominion there is limited to a few scattered trading stations along the western coast. It is divided into two provinces, north and south. Of these, the former contained, according to a census of 1874, 4095 native inhabitants, and the other 5512. The whole European population was only 236, the inhabitants of the entire colony thus numbering 9843.

Population.—There was a census of Denmark taken in 1870, according to which the population of the mother country was 1,784,741, of the Faroe Isles 9992, and of the other dependencies 117,409. On the 1st of February 1876 the following official estimate was made:—

Provinces.	Area in English square miles	Population.
Zealand and Moen .	2793	682,400
Bornholm .	221	33,500
Lolland and Falster.	640	93,100
Funen, Langeland, &c.	1302	245,400
Jutland	9597	845,500
	14,553	1,902,900
Faroe Islands . . .	495	10,600
Iceland	30,000	71,300
Greenland.	2,800
WEST INDIES.		
St Croix	60	22,600
St Thomas.	14	14,000
St John	13	1,000
Total,	45,135	2,032,200

Denmark proper has 130 inhabitants to the English square mile. The density of population is much greater on the islands than in Jutland, Zealand having nearly 250 inhabitants to the square mile. The increase in the population of the towns has of late years been very rapid, and has much exceeded that of the country districts. Of the provincial towns, the most prosperous is Aarhus, which, from being comparatively insignificant, has become the most important place in Jutland. The only exception to this rapid increase is in the case of the towns on the new German frontier, especially Fredericia and Ribe.

Emigration, which at one time was carried on to a considerable extent, has in recent years greatly diminished. Of the 2088 persons who left Denmark in 1875, 1678 emigrated to the United States of America, 329 to Australia, 47 to Canada, and 34 to other parts of America, including the Salt Lake City.

The Danes are a yellow-haired and blue-eyed Teutonic race, of middling stature, and still bearing traces of their kinship with the Northern Scandinavian peoples. Their habits of life resemble those of the North Germans even more than those of their friendly neighbours the Swedes. The independent tenure of the land by a vast number of small farmers, *bonder*, who are their own masters, gives an air of carelessness, almost of truancy, to the well-to-do Danish peasant. He is thoroughly well satisfied with himself, takes an eager interest in current politics, and is generally a fairly-educated man of extreme democratic principles. The gaiety of the Danes is surprising; they have nothing of the stolidity of the Germans, or the severity of the Norwegians. The townspeople show a bias in favour of French habits and fashions. The separation from the duchies of Schleswig and Holstein, which were more than half German, has intensified the national character; and there is now no portion of the Danish dominions, except perhaps in the West Indian islands, where a Scandinavian language is not spoken.

History—The original form of the word Denmark is Danmark, the march or border of the Daur, but whence the name Daur, or Danes, proceeded is undecided, and has given rise to endless antiquarian discussion. A traveller of the name of Pytheas, who lived more than three centuries before the Christian era, is the first to speak of a northern country, under the name of Thule, by which he is believed to have meant Jutland. At this time the inhabitants of Southern Scandinavia are supposed to have been Celts, and it was long after this that what Rask defined as the Sarmatic Invasion (the flooding of the north of Europe by emigrants from Asia) began to take place. These Goths, as they were called, came through Russia into Germany and Denmark, and passed on into Sweden across the Sound. It used to be supposed that they pushed before them the races of the Lapps and Finns, but the latest discoveries of archaeology tend to prove that these latter came from Siberia over the north of the Gulf of Bothnia, and met the Goths a little outside the Arctic Circle. The gods anciently worshipped in Denmark were the Æsir, a family of heroic deities in which the characteristics of the leaders of the Sarmatic Invasion are probably enshrined. The language spoken by all the Northern Goths was originally, or very early, called the *Donsk tunga*, or Danish tongue, which gave way in the 13th and 14th centuries, when the Danish supremacy was on the decline, to *Norrøna Mål*, or Norse speech. From the earliest historical accounts we possess it appears that Jutland was divided among a great number of petty chieftains, often at war with one another. These *små-konger*, or "little kings," as they were called, were, however, to some degree banded together, and entirely distinct from the eastern Danes of the islands. These also were ruled by a variety of chiefs, but they all recognized the supremacy of the king of Lejre, a city in Zealand somewhere near the present town of Reerskild. Western Denmark was known to the Northmen as Red Gotland, and consisted of all the mainland north of the Elbe, that is, Holstein, Schleswig, and Jutland. Island Gotland consisted of the islands, and of the provinces of Skaania and Bleking, that is, all the south of Sweden. During the rule of the Valdemar kings, the old chronicler, Saxo Grammaticus, recorded in Latin an immense number of mythical and semi-mythical stories concerning the old history of Denmark, and his chronicle

is a treasure-house of truth and falsehood. According to him, the country takes its name from a King Dan the Famous, who united the *små-konger* under his sole rule, and he was succeeded by a King Frode, with whom a golden age set in. The question of supremacy among the Scandinavian peoples was settled in favour of Sweden at the battle of Bravalla, which was fought, as is supposed, in the 8th century between Sigurd Ring, king of Sweden, and Harald Hildetand, king of Denmark; with this battle the purely mythic age closes. In 823 the gospel was first preached in Denmark by some Frankish monks sent by the emperor Louis le Debonaire. Little was done in the way of actual conversion, but the road was opened for future missionaries. The famous Ansgarius failed to impress the Danes, though he was consoled by his brilliant success among the Swedes. The Christians, however, began by degrees to be tolerated. The first king of all Denmark was Gorm the Old, who flourished between 860 and 936. He was the son of a king of Lejre, and by great administrative and strategical skill managed to absorb into his hereditary dominions not only all that is now included in Denmark, but Schleswig, Holstein, Skaania, and even some provinces in Norway. And besides gaining all this territory, he also pushed his conquests for a while as far as Smolensk and Kieff in Russia, as Aix-la-Chapelle in Germany, and as Sens in France, after besieging Paris.

At the period in question, or rather somewhat later, namely, about the early part of the 10th century, commences the authentic history of the country. As early as the 8th century the Danes were remarkable for their well-planned predatory expeditions by sea, as was proved by their repeated invasions of England, their occasional descents on Scotland, and their conquest of Normandy. To cross a sea of three or four hundred miles in breadth was a bold undertaking for men unacquainted with the use of the compass; but the number of islands in Denmark early accustomed the inhabitants to navigation, and gave them a practical dexterity in it.

The early establishment of the Danes in England, and the subsequent arrival of bodies of their countrymen, joined to the talents of two of their princes, Sweyn, or Svend, and Canute, enabled the latter to acquire the crown of England. Canute (or Knud) the Great completed the conquest begun by his father, and became king of England as well as of Denmark in the year 1018; he resided generally in the former country, and left the crown to his sons Harald and Harthaknud. On the death of the latter, without male heirs, the Danish dynasty in England came to a close in 1012.

The feudal system was introduced in the 12th century, which, as well as the 13th, was marked in Denmark by contentions between the sovereign and the barons. About the 13th century the population of the towns in Denmark, as in Germany, though still very small, became such as to entitle them to obtain from the Crown charters of incorporation, and an exemption from the control of the barons, in whom was vested almost the whole property of the land. A regular constitution began now to be formed in Denmark, and the towns sent deputies or representatives to the States, or Parliament, which, it was enacted, should meet once a year. It was also ordered that the laws should be uniform throughout the kingdom, and that no tax should be imposed without the authority of Parliament.

It is unnecessary to recapitulate the successive sovereigns of Denmark in the Middle Ages, of whom few were of distinguished ability. The names of most frequent occurrence among them in these early times were Knud, Valdemar, and Erik. Those of Christiern, or Christian, and Frederick were of later date. One of the most remarkable of the sovereigns in the Middle Ages was Valdemar II., who suc-

ceeded to the crown in 1202, and who was the most prosperous and afterwards the most unfortunate of Danish kings. He conquered Holstein and Pomerania, and in 1217 the emperor recognized his authority over a large part of the north of Germany,—all in fact north of the Elbe. Valdemar then pushed his forces into Norway and Sweden, but with less success; but in 1219 he set out on a vast crusade against the Pagans in Esthonia, the whole of which he overran, forcibly converting the inhabitants. It was in this war that Denmark commenced to use the Dannebrog, or national standard, a white cross on a blood-red field. On his return, in the midst of his magnificent success, a great calamity befell Valdemar; he was treacherously captured at Lyö in 1223 by the duke of Schwerin, and imprisoned for several years in a dungeon in Mecklenburg; but he finally escaped, and ruled until his death in 1241.

The chief mercantile intercourse of Denmark in those times was with Lubeck and the north-west of Germany. To the Baltic Lubeck was nearly what Venice was to the Mediterranean, the earliest commercial town of consequence. There was also some traffic from Denmark to the mouths of the Vistula,—the name of Dautzie, or Dansvik (Danish town or port), indicating that a Danish colony, aware of the advantages of the situation, had established itself there.

During the same period (the 14th century), the association of the Hanse Towns had acquired considerable strength, and asserted strenuously the freedom of commerce in the north of Europe. Denmark, commanding the entrance into the Baltic, was the power most interested in laying merchant vessels under a toll or regular contribution; and the result was repeated contentions, followed at times by open war, between the Danish Government and this powerful confederacy.

The most important event, however, in the history of Denmark, or indeed of Scandinavia, in the Middle Ages, was the conjunct submission of Sweden, Denmark, and Norway to one sovereign, by the compact or union of Calmar, in the year 1397. Valdemar III., king of Denmark, having died in the year 1378, left two daughters, of whom the second, Margaret, was married to Hakon VI., king of Norway. On the demise of her husband the government of Norway remained in her hands; and afterwards, on the death of her son, who had been declared king of Denmark, the States, or Parliament, of that country fixed this princess on the throne, on her consenting to extend and secure their rights and privileges. The States of Norway followed their example; so that Margaret, finding herself seated on the thrones of Denmark and Norway, directed her attention to that of Sweden, the succession to which would have fallen to her husband Hakon had he survived. The Swedes were divided into two parties—that of Margaret, and that of a duke of Mecklenburg. An appeal to arms took place, and the result was favourable to the cause of the queen, her competitor being defeated and made prisoner. In 1397 the States of the three kingdoms were convoked at Calmar, a town situated in the south of Sweden. There they concurred in passing the Act known as the Union of Calmar, by which the three kingdoms were henceforth to be under one sovereign, who should, however, be bound to govern each according to its respective laws and customs. To guard against their separation, it was enacted that, if a sovereign should leave several sons, one of them only should be the ruler of the three kingdoms, and in the event of the reigning king or queen dying without children, the senators and parliamentary deputies of the three kingdoms should jointly proceed to the election of another joint sovereign.

Such were the precautions taken by Margaret, who has been called the Semiramis of the North, in order to banish

war and political dissensions from Scandinavia. For a time they were successful, and peace and concord were maintained during the lifetime of the queen and her two successors. But the union, as regarded the Swedes, was far from being cordial; they submitted reluctantly to a foreign family, and considered themselves as obliged to act in subserviency to the political views of Denmark. At last the severity, or rather the cruelty, of one of the Danish kings, Christian II., and the appearance of an able assertor of Swedish independence in Gustavus Vasa, led to an insurrection, which, beginning in the northern province of Dalecarlia, extended throughout Sweden, and led to a definitive separation of the two crowns in the year 1523.

In 1490 the reigning king of Denmark made a commercial treaty with Henry VII. of England, by which the English engaged to pay the Sound dues on all vessels entering or returning from the Baltic; and in return they were allowed to have mercantile consuls in the chief seaports of Denmark and Norway. By this time the extension of trade had given rise in Denmark, as in England, to a middle class, among whom the sovereign found in each country the means of balancing the political weight of the nobility; hence a grant was made by the kings of Denmark of various privileges to traders, and of relief from a number of local imposts on the transit of merchandise.

The rude habits of the age were strongly marked by the difficulty which the Danish Government found in putting a stop to the practice of plundering merchantmen shipwrecked on the coast. The practice was to collect in the vicinity of a wreck such a number of the inhabitants as to prevent the master or mariners from opposing the seizure of the merchandise. Even bishops residing on the coast, though humane in their treatment of the crews, did not scruple to aid in taking forcible possession of the cargo; and it is a remarkable fact, that a law passed by the king, about the year 1521, for the prevention of these practices, was abrogated and publicly burned at the instance of the barons and clergy a few years after, when a new sovereign had succeeded to the crown.

The doctrines of the Reformation found their way into Denmark at an early date. Frederick I., who began to reign in 1525, and had formerly been duke of Holstein, in that year embraced the Protestant religion. The inhabitants of Denmark being divided between the Catholics and Protestants, Frederick began by an edict for tolerating both religions. An assembly of the States, or Parliament, next passed a solemn Act for the free preaching of the Protestant faith, and for allowing ecclesiastics of any class to marry and reside in any part of the kingdom. The consequence of this was a reduction of the number of the inmates of abbeys, monasteries, and convents, along with the general diffusion of the Lutheran faith throughout the kingdom. This rapid progress enabled the succeeding sovereign, Christian III., to act like Henry VIII. of England, by annexing the church-lands to the Crown, and strengthening the power of the sovereign at the expense of that of the clergy.

The great religious war which broke out in 1618 for the first time fixed the attention of Europe on Denmark. The victories of the imperial general Tilly, and of Maximilian of Bavaria, over the Protestants, appeared to make the Emperor Ferdinand, who was the head of the Catholic party, complete master of Germany, when Christian IV. of Denmark, encouraged by England and France, determined to take up the Protestant cause as a principal in the general contest. But being weakly supported by his allies, the Danish king, after one year's campaign, was obliged to flee before the victorious army of Wallenstein (1626), and to sue for peace, which was concluded at Lübeck in 1629. By the stipulations of this peace Denmark bound itself never

Pultowa, in the year 1709, and his subsequent flight into Turkey, the king of Denmark eagerly embraced the opportunity of renewing hostilities with Sweden, and invaded both Holstein in the south and the province of Skaania to the north. Skaania was badly provided with troops, but it had officers trained in one of the best military schools of the age, and a peasantry full of national antipathy to the Danes. The result was a spirited attack on the invading army, followed by its defeat and precipitate flight into Denmark. The war was then carried on with alternate success in different parts—in Pomerania, in Holstein, and in Norway; until at last the military career of Charles XII. came unexpectedly to a close in the end of 1718. Some time afterwards, negotiations were opened between Sweden and Denmark, under the mediation of England, and ended in 1720 in a definitive treaty of peace, concluded at Stockholm. It was then that Sweden lost all the advantages gained since the Peace of Westphalia, and that George I. of England, as elector of Hanover, Prussia, and Peter the Great shared with Denmark the spoil of Sweden. From that time no danger threatened Denmark from the side of its neighbour, though the cessation of the rivalry was more perceptible in the decline of Sweden than in the progress of Denmark.

The Danish Government had now ample experience of the sacrifices attendant on war, and of the expediency, to a state of such limited power, of avoiding political collisions. It consequently adopted a peace policy, to which it has almost ever since endeavoured to adhere.

It was towards the middle of the 18th century that the family of Bernstorff became known in the councils of Denmark,—the first minister of that name, a man of superior talent and information, having come forward at that time. By the prudence of the ministry, and the pacific disposition of the sovereign, Denmark was kept from taking part in the war begun in Germany in 1740, as well as in the more general contest begun in the same country in 1756.

Frederick V. of Denmark was twice married, and died in 1766, leaving a son by each wife. The crown devolved of course on the elder, his son by the first wife, who took the name of Christian VII. He was a weak prince, and listened too readily to the insinuations of his step-mother, whose secret wish was to secure the succession of the crown to her own son, and who did not scruple, with that view, to sow discord between Christian and his young consort, a princess of England, the youngest daughter of George II. The circumstances were these. A German adventurer named Struensee had ingratiated himself into the favour of Frederick V., the late king, and had found means to be appointed his prime minister—a situation which he was ill qualified to fill. He continued to hold that office under Christian, and was introduced to the young queen as her husband's confidential minister. On this the queen husband founded an intrigue, and succeeded in persuading the king that the queen, in concert with Struensee and his friend Count Brandt, had formed a project to set him aside, and to get herself declared regent of the kingdom. By working on the fears of this weak prince, the queen dowager prevailed on him to authorize the arrest of the queen and the two ministers. The latter were thrown into prison, and Struensee was accused of having abused his authority as minister, and of other criminal acts. As there was no proof of these acts, recourse was had to the barbarous alternative of torture, the dread of which led Struensee to declare, in the form of a confession, much to the injury of the young queen, which is now considered as unfounded. This, however, did not enable him to escape, for he and Count Brandt were both beheaded in April 1772; whilst the queen consort was, at the instance of the British

Government, allowed to retire and to pass the remainder of her short life at Zell, in Hanover, repeatedly but fruitlessly demanding an open trial. This ill-fated princess died in her twenty-third year, without the satisfaction of knowing that the author of her misfortunes, the queen dowager, had lost her influence at the court of Denmark.

One of the principal political questions between Great Britain and Denmark occurred in 1780, during the war carried on by England against France, Spain, and the North American colonies. During that arduous contest, England, superior at sea, had no difficulty in obtaining, by her own merchantmen, a supply of hemp, cordage, and other naval stores from the Baltic, whilst France and Spain trusted to receiving such supplies by neutral vessels. But the English Government denied the right of neutrals to carry warlike stores; and the northern powers, headed by the ambitious Catherine of Russia, entered into a compact, called the Armed Neutrality, by which, without resorting to actual hostility, they sought to overawe England, and to continue the questionable traffic. Happily no bloodshed followed this diplomatic menace, and the question fell to the ground in 1782, on the negotiation for a general peace.

The king of Denmark, subject all along to imbecility, became after 1784 quite incapable of governing. His son, the crown prince, was therefore appointed regent, and soon passed several judicious enactments. The peasants living on the crown lands were gradually emancipated—an example followed by a number of the nobility on their respective estates. In the abolition of the African slave trade Denmark had the honour of taking the lead among the Governments of Europe. The crown prince, guided by the counsels of Count Bernstorff, son of the minister already mentioned, long remained neutral in the political convulsion engendered by the French Revolution. He continued to adhere steadfastly to this plan until in 1801 the emperor Paul of Russia having, as in the case of the Armed Neutrality, formed a compact of the northern powers hostile to England, a British fleet was sent into the Baltic under the orders of Sir Hyde Parker, with Lord Nelson as his second in command.

It was this fleet which taught the Danes that their capital was not impregnable, and that the long line of men-of-war moored in front of the harbour was an insufficient defence against such enterprising opponents. The attack took place on 2d of April 1801; and the resistance of the Danes was spirited, but fruitless. The loss of the English in killed and wounded exceeded 1000 men, but that of their opponents was much greater, and most of their shipping was destroyed. Happily little injury was done to the capital. A cessation of hostilities took place forthwith, and was followed by a treaty of peace. The death of Paul, which occurred soon afterwards, dissolved the compact between the northern courts.

But no treaty of peace could be regarded as permanent during the ascendancy of Napoleon. After defeating first Austria and then Prussia, that extraordinary man found means to obtain the confidence of the emperor Alexander of Russia, and in the autumn of 1807 threatened to make Denmark take part in the war against England. Although the Danish Government discovered no intention to violate its neutrality, the English ministers, eager to please the public by acting on a system of vigour, despatched to the Baltic both a fleet and an army, in order to compel the surrender of the Danish navy, upon condition of its being restored in the event of peace. To such a demand the crown prince gave an immediate negative, declaring that he was both able and willing to maintain his neutrality, and that his fleet could not be given up on any such condition. On this the English army landed near Copenhagen, laid siege to that city, and soon obliged the Govern-

ment to purchase its safety by surrendering the whole of its naval force.

This act, the most questionable in point of justice of any committed by the British Government during the war, can hardly be defended on the score of policy. The resentment felt on the occasion by the emperor of Russia was so great as to deprive England during four arduous years of the benefit of his alliance; and the seizure of the Danish fleet so exasperated the crown prince and the nation at large, that they forthwith declared war against England, throwing themselves completely into the arms of France.

The hostilities between England and Denmark were carried on by sea, partly at the entrance of the Baltic, and partly on the coast of Norway. These consisted of a series of actions between single vessels or small detachments, in which the Danes fought always with spirit, and not unfrequently with success. In regard to trade, both nations suffered severely,—the British merchantmen in the Baltic being much annoyed by Danish cruisers, whilst the foreign trade of Denmark was in a manner suspended, through the naval superiority of England.

The situation of the two countries continued on the same footing during five years, when at last the overthrow of Bonaparte in Russia opened a hope of deliverance to those who were involuntarily his allies. The Danish Government would now gladly have made peace with England; but the latter, in order to secure the cordial co-operation of Russia and Sweden, had gone so far as to guarantee to these powers the cession of Norway on the part of Denmark. The Danes, ill prepared for so great a sacrifice, continued their connection with France during the eventful year 1813; but at the close of that campaign a superior force was directed by the allied sovereigns against Holstein, and the result was, first an armistice, and eventually a treaty of peace in January 1814. The terms of the peace were, that Denmark should cede Norway to Sweden, and that Sweden, in return, should give up Pomerania to Denmark. But Pomerania, being too distant to form a suitable appendage to the Danish territory, was exchanged for a sum of money and a small district in Lauenburg adjoining Holstein. On the part of England, the conquests made from Denmark in the East and West Indies were restored,—all, in short, that had been occupied by British troops, excepting Heligoland.

After the Congress of Vienna, by which the extent of the Danish monarchy was considerably reduced, the court of Copenhagen was from time to time disquieted by a spirit of discontent manifesting itself in the duchies, and especially in that of Holstein, the outbreak of which in 1848 threatened the monarchy with complete dissolution. A short recapitulation of the relation of the different parts of the kingdom to each other will furnish a key to the better comprehension of these internal troubles. When Christian I. of the house of Oldenburg ascended the throne of Denmark in 1448, he was at the same time elected duke of Schleswig and Holstein, while his younger brother received Oldenburg and Delmenhorst. In 1544 the older branch was again divided into two lines, that of the royal house of Denmark, and that of the dukes of Holstein-Gottorp. Several collateral branches arose afterwards, of which those that survived were—the Augustenburg and Glücksburg branches belonging to the royal line, and the ducal Holstein-Gottorp branch, the head of which was Peter III. of Russia. In 1762 Peter threatened Denmark with a war, the avowed object of which was the recovery of Schleswig, which had been expressly guaranteed to the Danish Crown by England and France at the Peace of Stockholm (1720). His sudden dethronement, however, prevented him from putting this design into execution. The empress Catharine agreed to an accommodation, which was signed at Copenhagen in

1764, and subsequently confirmed by the emperor Paul, 1773, by which the ducal part of Schleswig was ceded to the Crown of Denmark. The czar abandoned also his part of Holstein in exchange for Oldenburg and Delmenhorst, which he transferred to the younger branch of the Gottorp family. According to the scheme of Germanic organization adopted by the Congress of Vienna, the king of Denmark was declared member of the Germanic body on account of Holstein and Lauenburg, invested with three votes in the General Assembly, and had a place, the tenth in rank, in the ordinary diet.

After the restoration of peace in 1815, the states of the duchy of Holstein, never so cordially blended with Denmark as those of Schleswig, began to show their discontent at the continued non-convocation of their own assemblies despite the assurances of Frederick VI. The preparation of a new constitution for the whole kingdom was the main pretext by which the court evaded the claims of the petitioners, who met, however, with no better success from the German diet, before which they brought their complaints in 1822. After the stirring year of 1830, the movement in the duchies, soon to degenerate into a mutual animosity between the Danish and German population, became more general. The scheme of the court to meet their demands by the establishment of separate deliberative assemblies for each of the provinces failed to satisfy the Holsteiners, who continually urged the revival of their long-neglected local laws and privileges. Nor were matters changed at the accession in 1838 of Christian VIII., a prince noted for his popular sympathies and liberal principles. The feeling of national animosity was greatly increased by the issue of certain orders for Schleswig, which tended to encourage the culture of the Danish language to the prejudice of the German. The elements of a revolution being thus in readiness waited only for some impulse to break forth into action. Christian died in the very beginning of 1848, before the outbreak of the French revolution in February, and left his throne to his son Frederick VII., who had scarcely received the royal unction when half of his subjects rose in rebellion against him.

In March 1848 Prince Frederick of Augustenburg, having gained over the garrison of Rendsburg, put himself at the head of a provisional Government proclaimed at Kiel. A Danish army, marching into Schleswig, easily reduced the duchy as far as the banks of the Eider; but, in the meantime, the new national assembly of Germany resolved upon the incorporation of Schleswig; and the king of Prussia followed up their resolution by sending an army into the duchies under the command of General Wrangel. The Prussian general, after driving the Danes from Schleswig, marched into Jutland; but on the 26th of August an armistice was signed at Malmoe, and an agreement came to by which the government of the duchies was intrusted to a commission of five members—two nominated by Prussia, two by Denmark, and the fifth by the common consent of the four, Denmark being also promised an indemnification for the requisitions made in Jutland.

After the expiry of the armistice, the war was renewed with the aid of Prussian troops and other troops of the confederacy (from March to July 1849), when Prussia signed a second armistice for six months. The duchies now continued to increase their own troops, being determined to carry on the war at their own charge without the aid of Prussia, whose policy they stigmatized as inconsistent and treacherous. The chief command of the Schleswig-Holstein army was intrusted to General Willisen, a scientific and able soldier; but henceforth the Danes had little to fear, especially as the cry of German unity brought but an insignificant number of volunteers to the camp of the Holsteiners. The last victory of the Danes, under generals

Krogh and Schlepegrell, was at the battle of Idsted (July 23). Near this small village, protected by lakes and bogs, Willisen lay encamped with his centre, his right wing at Wedelspung, extending along the Lake Langso, his left spreading along the Arnholtz lake. The Danes, approaching on the high road from Flensburg to Schleswig, attacked the enemy on all sides; and, after having been repeatedly repulsed, they succeeded in driving the Schleswig-Holsteiners from all their positions. The forces engaged on each side were about 30,000; the number of killed and wounded on both sides was upwards of 7000.

After the victory of Idsted, the Danes could hardly expect to meet with any serious resistance, and the confidence of the court of Copenhagen was further increased by the peace which was concluded with Prussia (July 1850), by which the latter abandoned the duchies to their own fate, and soon afterwards aided in their subjection. The sole question of importance which now awaited its solution was the order of succession, which the European powers thought to be of such importance as to delay its final settlement till 1852.

The extinction of the male line in King Frederick was an event foreseen by the king, the people, and the foreign powers. After protracted negotiations between the different courts, the representatives of England, France, Austria, Russia, Prussia, and Sweden, a treaty relative to the succession was signed in London, May 8, 1852. According to this protocol, in case of default of male issue in the direct line of Frederick VII., the crown was to pass to Prince Christian of Glücksburg, and his wife the Princess Louisa of Hesse, who, through her mother, Princess Charlotte of Denmark, was the niece of King Christian VIII.

The treaty of London did not fulfil the expectations of the signatories as to a settlement of the agitation in the duchies. The duke of Augustenburg had accepted the pardon held out to him on condition that his family resigned all claim to the sovereignty of the duchies, but he continued to stir up foreign nations about his rights, and when he died his son Frederick maintained the family pretensions. At last, in the autumn of 1863, Frederick VII. died very suddenly at the castle of Glücksburg, in Schleswig, the seat of his appointed successor. As soon as the ministry in Copenhagen received news of his death, Prince Christian of Glücksburg was proclaimed king as Christian IX., and the young duke of Augustenburg appeared in Schleswig, assuming the title of Frederick VIII. The claims of the pretender were supported by Prussia, Austria, and other German states, and before the year was out Generals Gablenz and Wrangel occupied the duchies in command of Austrian and Prussian troops. The attitude of Germany was in the highest degree peremptory, and Denmark was called upon to give up Schleswig-Holstein to military occupation by Prussia and Austria until the claims of the duke of Augustenburg were settled. In its dilemma the Danish Government applied to England and to France, and receiving from these powers what it rightly or wrongly considered as encouragement, it declared war with Germany in the early part of 1864. The Danes sent their general, De Meza, with 40,000 men to defend the Dannewerk, the ancient line of defences stretching right across the peninsula from the North Sea to the Baltic. The movements of General De Meza were not, however, successful; the Dannewerk, popularly supposed to be impregnable, was first outflanked and then stormed, and the Danish army fell back on the heights of Dybbol, near Flensburg, which was strongly fortified, and took up a position behind it, across the Little Belt, in the island of Als. This defeat caused almost a panic in the country, and, finding

that England and France had no intention of aiding them, the Danes felt the danger of annihilation close upon them. The courage of the little nation, however, was heroic, and they made a splendid stand against their countless opponents. General Gerlach was sent to replace the unlucky De Meza; the heights of Dybbol were harder to take than the Germans had supposed, but they fell at last, and with them the strong position of Sonderburg, in the island of Als. The Germans pushed northwards until they overran every part of the mainland, as far as the extreme north of Jutland. It seemed as though Denmark must cease to exist among the nations of Europe, but the Danes at last gave way, and were content to accept the terms of the Peace of Vienna, in October 1864, by which Christian IX. renounced all claim to Lauenburg, Holstein, and Schleswig, and agreed to have no voice in the final disposal of those provinces.

For the next two years Europe waited to see Prussia restore North Schleswig and Als, in which Danish is the popular language, and which Austria had demanded should be restored to Denmark in case the inhabitants should express that as their wish by a *plébiscite*. When the war broke out between Austria and Prussia in 1866, and resulted in the humiliation of Austria, the chances of restoration passed away, and the duchies have remained an integral part of Prussia. Notwithstanding her dismemberment, Denmark has prospered to an astonishing degree, and her material fortunes have been constantly in the ascendant. Her only trouble within the last decade has arisen from the dissensions in the two houses of assembly, and in the spread of dangerous communistic opinions.

The following is a list of the monarchs of Denmark since the unification of the kingdom under Gorm the Old, with the dates of their accession —

GORM'S LINE.		Christopher II.	1319
Gorm the Old, <i>circa</i>	860	Interregnum	1332
Harald Bluetooth	938	Valdemar III.	1340
Svend Twybeard	985	Olaf II.	1375
Harald	1014	Margaret.	1387
Knud the Great.	1018	DENMARK AND NORWAY.	
Harthaknud	1035	Erik of Pomerania.	1412
SUBJECT TO NORWAY.		Christopher III.	1439
Magnus the Good.. . . .	1042	THE HOUSE OF OLDENBURG.	
THE HOUSE OF ESTRIDSEN		Christian I.. . . .	1448
Svend Estridsen	1047	Hans	1481
Harald Heyn	1076	Christian II	1513
Knud the Saint.. . . .	1080	Frederick I	1523
Olaf Hunger	1086	Christian III.. . . .	1533
Erik Eiegod	1095	Frederick II	1559
Niels	1103	Christian IV.	1588
Erik Emun	1134	Frederick III.	1648
Erik the Lamb	1137	Christian V.	1670
Knud V. and Svend III.	1147	Frederick IV.	1699
Valdemar I	1157	Christian VI.	1730
Knud VI	1182	Frederick V	1746
Valdemar II	1202	Christian VII	1766
Erik IV	1241	Frederick VI.	1808
Abel.	1250	Christian VIII	1839
Christopher I.	1252	Frederick VII.	1848
Erik V.	1259	HOUSE OF GLÜCKSBURG	
Erik VI.	1286	Christian IX.	1863

Literature.

The present language of Denmark is derived directly from the same source as that of Sweden, and the parent of both is the old Scandinavian (see SCANDINAVIAN LANGUAGES). In Iceland this tongue, with some modifications, has remained in use, and until about 1100 it was the literary language of the whole of Scandinavia. The influence of Low German first, and High German afterwards, has had the effect of drawing modern Danish constantly further from this early type. The difference began to show itself in the 12th century. Rask, and after him Petersen, have distin-

positive legacy to literature. Nor in any series of comedies in existence is deceit so rarely sacrificed to a desire for popularity or a false sense of wit.

Holberg founded no school of immediate imitators, but his stimulating influence was rapid and general. After the great conflagration, the university of Copenhagen was reopened in 1742, and under the auspices of the historian Gram, who founded the Society of Sciences, it recommended an active intellectual life. In 1744 Langebek founded the Society for the Improvement of the Danish Language, which opened the field of philology. In jurisprudence Andreas Høier represented the new impulse, and in zoology Erik Pontoppidan, the younger. This last name represents a life-long activity in many branches of literature. From Holberg's college of Sorø, two learned professors, Sneedorff and Kraft, disseminated the seeds of a wider culture. All these men were aided by the generous and enlightened patronage of Frederick V. A little later on, the German poet Klopstock settled in Copenhagen, bringing with him the prestige of his great reputation, and he had a strong influence in Germanizing Denmark. He founded, however, the Society for the Fine Arts, and had it richly endowed. The first prize offered was won by C. B. Tullin (1728-1765) for his beautiful poem of *May day*. Tullin, a Norwegian by birth, represents the first accession of a study of external nature in Danish poetry; he was an ardent disciple of the English poet Thomson. Ambrosius Stub (1707-1758) was a lyrical poet of great sweetness, born before his due time, whose poems, not published till 1782, belong to a later age than their author.

The Lyrical Revival—Between 1742 and 1749, that is to say, at the very climax of the personal activity of Holberg, eight poets were born, who were destined to enrich the language with its first group of lyrical blossoms. Of these the two eldest, Wessel and Ewald, were men of extraordinary genius, and destined to fascinate the attention of posterity, not only by the brilliance of their productions, but by the suffering and brevity of their lives. Joannes Ewald (1743-1781) was not only the greatest Danish lyricist of the 18th century, but he had few rivals in the whole of Europe. As a dramatist, pure and simple, his bird-like instinct of song carried him too often into a sphere too exalted for the stage, but he has written nothing that is not stamped with the exquisite quality of distinction. In *The Fishers*, which contains the Danish national song, *Kong Kristian stod*, the lyrical element is most full and charming; in *Rolf Krage*, and *Balder's Death*, Ewald was the first to foresee the revival of a taste for Scandinavian history and mythology; *The Brutal Clappers*, a polemical drama, shows that he also possessed a keen sense of humour. Wessel (1742-1785) excited even greater hopes in his contemporaries, but left less that is immortal behind him. After the death of Holberg, the affectation of Gallicism had reappeared in Denmark, and the tragedies of Voltaire, with their stilted rhetoric, were the most popular dramas of the day. Nordahl Brun (1745-1816), a young writer who did better things later on, gave the finishing touch to the exotic absurdity by bringing out a wretched piece called *Zarina*, which was hailed by the press as the first original Danish tragedy, although Ewald's exquisite *Rolf Krage*, which truly merited that title, had appeared two years before. Wessel, who up to that time had only been known as the president of a club of wits, immediately wrote *Love without Stockings*, in which a plot of the most abject triviality is worked out in strict accordance with the rules of French tragedy, and in most pompous and pathetic Alexandrines. The effect of this piece was magical; the Royal Theatre ejected its cuckoo-brood of French plays, and even the Italian opera. It was now essential that every performance should be national, and in

the Danish language. To supply the place of the opera, native musicians, and especially Hartmann, set the dramas of Ewald and others, and thus the Danish school of music originated. Of the other poets of the revival the most important were born in Norway. Nordahl Brun, Claus Frimann (1746-1829), Claus Fasting (1746-1791), C. H. Pram (1756-1821), and Edvard Storm (1749-1794) were associates and mainly fellow-students at Copenhagen, where they introduced a style peculiar to themselves, and distinct from that of the true Danes. Their lyrics celebrated the mountains and rivers of the magnificent country they had left; and, while introducing images and scenery unfamiliar to the inhabitants of the monotonous Denmark, they enriched the language with new words and phrases. This group of writers are now claimed by the Norwegians as the founders of a Norwegian literature; but their true place is certainly among the Danes, to whom they primarily appealed. They added nothing to the development of the drama, except in the person of N. K. Bredal (1733-1778), who became director of the Royal Danish Theatre, and the writer of some mediocre plays.

To the same period belong a few prose writers of eminence. Werner Abrahamson (1744-1812) was the first æsthetic critic Denmark produced. Johan Clemens Tode (1736-1806) was eminent in many branches of science, but especially as a medical writer. Ove Malling (1748-1829) was an untiring collector of historical data, which he annotated in a lively style. Two historians of more definite claim on our attention are Peter Frederik Suhm (1728-98) and Ove Guldberg (1731-1808). In theology Bastholm (1740-1819) and Balle (1744-1816) demand a reference. But the only really great prose-writer of the period was the Norwegian Niels Treschow (1751-1833), whose philosophical works are composed in an admirably lucid style, and are distinguished for their depth and originality.

The poetical revival sunk in the next generation to a more mechanical level. The number of writers of some talent was very great, but genius was wanting. Two intimate friends, Rein (1760-1821) and Zethitz (1761-1821), attempted, with indifferent success, to continue the tradition of the Norwegian group. Thomas Thaarup (1749-1821) was a fluent and eloquent writer of occasional poems. The early death of Ole Samsøe (1759-1796) prevented the development of a dramatic talent that gave rare promise. But while poetry languished, prose, for the first time, began to flourish in Denmark. Knud Lyne Rahbek (1760-1830) was a pleasing novelist, a dramatist of some merit, a pathetic elegist, and a witty song-writer; he was also a man full of the literary instinct, and through a long life he never ceased to busy himself with editing the works of the older poets, and spreading among the people a knowledge of Danish literature. Peter Andreas Heiberg (1758-1841) is best known as the husband and the father of two of the greatest Danish writers, but he was himself a political and æsthetic critic of note. He was exiled from Denmark in company with Malte Conrad Brun (1775-1826), who settled in Paris, and attained a world-wide reputation as a geographer. O. C. Olufsen (1764-1827) was a writer on geography, zoology, and political economy. Rasmus Nyrup (1759-1829) expended an immense energy in the compilation of admirable works on the history of language and literature. From 1778 to his death he exercised a great power in the statistical and critical departments of letters. The best historian of this period, however, was Engelstoft (1774-1850), and the most brilliant theologian Bishop Mynster (1775-1854). In the annals of modern science Hans Christian Oersted (1777-1851) is a name universally honoured. He explained his inventions and described his discoveries in language so lucid and so char-

acteristic that he claims an honoured place in the literature of the country of whose culture, in other branches, he is one of the most distinguished ornaments.

We pause on the threshold of the romantic movement to record the name of a man of great genius, whose work was entirely independent of the influences around him. Jens Baggesen (1764-1826) is the greatest comic poet that Denmark has produced. As a dramatist he failed; as a philosophic and critical writer he has not retained the attention he once commanded; but as a satirist and witty lyricist he has no rival among the Danes. In his hands the difficulties of the language disappear; he performs with the utmost ease extraordinary *tour de force* of style. His astonishing talents were wasted on trifling themes and in a fruitless resistance to the modern spirit in literature.

Romanticism — With the beginning of the 19th century the new light in philosophy and poetry, which radiated from Germany through all parts of Europe, found its way into Denmark also. In scarcely any country was the result so rapid or so brilliant. There arose in Denmark a school of poets who created for themselves a reputation in all parts of Europe, and would have done honour to any nation or any age. The splendid cultivation of metrical art threw other branches into the shade; and the epoch of which we are about to speak is eminent above all for mastery over verse. The swallow who heralded the summer was a German by birth, Adolph Schaack-Staffeldt (1769-1826), who came over to Copenhagen from Pomerania, and prepared the way for the new movement. Since Ewald no one had written Danish lyrical verse so exquisitely as Schaack-Staffeldt, and the depth and scientific precision of his thought won him a title which he has preserved, of being the first philosophic poet of Denmark. The writings of this man are the deepest and most serious which Denmark has produced, and at his best he yields to no one in choice and skilful use of expression. This sweet song of Schaack-Staffeldt's, however, was early silenced by the louder choir that one by one broke into music around him. It was Adam Gottlob Oehlenschläger (1779-1850), the greatest poet of Denmark, who was to bring about the new romantic movement. Oehlenschläger had already written a great many verses in the old semi-didactic, semi-rhetorical style, when in 1802 he happened to meet the young Norwegian Henrik Steffens (1773-1845), who had just returned from a scientific tour in Germany, full of the doctrines of Schelling. Under the immediate direction of Steffens, Oehlenschläger commenced an entirely new poetic style, and destroyed all his earlier verses. A new epoch in the language began, and the rapidity and matchless facility of the new poetry was the wonder of Steffens himself. The old Scandinavian mythology lived in the hands of Oehlenschläger exactly as the classical Greek religion was born again in Keats. After twelve years of ceaseless labour, and the creation of a whole library of great works, the vigour of Oehlenschläger somewhat suddenly waned, and he lived for nearly forty years longer, completely superseded by younger men, and producing few and mainly inferior works. Since and except Holberg no author has possessed so great an influence on Danish letters as Oehlenschläger. He aroused in his people the slumbering sense of their Scandinavian nationality.

The retirement of Oehlenschläger comparatively early in life, left the way open for the development of his younger contemporaries, among whom several had genius little inferior to his own. Steen Steensen Blicher (1782-1848) was a Jutlander, and preserved all through life the characteristics of his sterile and sombre fatherland. After a struggling youth of great poverty, he at length, in 1814, published a volume of lyrical poems; and in 1817 he attracted considerable attention by his descriptive poem of

The Tour in Jutland. His real genius, however, did not lie in the direction of verse; and his first signal success was with a volume of stories in 1824, which were rapidly followed by others for the next twelve years. Blicher is a stern realist, in many points akin to Crabbe, and takes a singular position among the romantic idealists of the period, being like them, however, in the love of precise and choice language, and hatred of the mere commonplace of imaginative writing.

Nikolai Frederik Severin Grundtvig (1783-1872), like Oehlenschläger, learned the principles of the German romanticism from the lips of Steffens. He adopted the idea of introducing the Old Scandinavian element into art, and even into life, still more earnestly than the older poet. There was scarcely any branch of letters in which Grundtvig did not distinguish himself; he was equally influential as a politician, a theologian, a poet, and a social economist.

Bernhard Severin Ingemann (1789-1862) was a man in every way unlike the last-mentioned poet. A mild, idyllic mind, delicately appreciative of the gentler manifestations of nature, and shrinking from violent expression of any sort, distinguished the amiable Ingemann. His greatest contributions to Danish literature are the historical romances which he published in middle life, strongly under the influence of the novels of Sir Walter Scott. Several of these, particularly *Faldeknæ Sier* and *Prince Otto of Denmark*, have enjoyed and still enjoy a boundless popularity. He is remarkable as the first importer into Scandinavia of the historical novel, since very generally cultivated.

Johannes Carsten Hauch (1790-1872) first distinguished himself as a disciple of Oehlenschläger, and fought under him in the strife against the old school and Baggesen. But the master misunderstood the disciple; and the harsh repulse of Oehlenschläger silenced Hauch for many years. He possessed, however, a strong and fluent genius, which eventually made itself heard in a multitude of volumes, poems, dramas, and novels. All that Hauch wrote is marked by great qualities, and by distinction; he had a native bias towards the mystical, which, however, he learned to keep in abeyance.

Johan Ludvig Heiberg (1791-1860) as a critic ruled the world of Danish taste for many years, and his lyrical and dramatic works were signally successful. He had the genius of good taste, and his witty and delicate productions stand almost unique in the literature of his country.

The mother of J. L. Heiberg, the Countess Gyllembourg (1773-1856), was the greatest authoress which Denmark has possessed. She wrote a large number of anonymous novels, which began to appear in 1828 in her son's journal, *The Flying Post*. Her knowledge of life, her sparkling wit, and her almost faultless style, make these short stories, the authorship of which remained unknown until her death, master-pieces of their kind.

Ludvig Adolf Bødtker (1793-1874) wrote only one single volume of lyrical poems, which he gradually enlarged in succeeding editions. He was a consummate artist in verse, and his impressions are given with the most delicate exactitude of phrase, and in a very fine strain of imagination. Most of his poems deal with Italian life, which he learned to know thoroughly during a long residence in Rome. He was the secretary of Thorwaldsen for a considerable time.

Christian Winther (1796-1876) made the island of Zealand his loving study, and that province of Denmark belongs to him no less thoroughly than the Cumberland lakes belong to Wordsworth. Between the latter poet and Winther there was much resemblance. He was, without compeer, the greatest pastoral lyricist of Denmark. His ex-

quisite strains, in which pure imagination is blended with most accurate and realistic descriptions of scenery and rural life, have an extraordinary charm not easily described.

The youngest of the great poets born during the last twenty years of the 18th century was Henrik Hertz (1798-1870). He was the most tropical and splendid lyricist of the period, a sort of troubadour, with little of the Scandinavian element in his writing. It is true that in some of his dramas, particularly in *Svend Dyring's House*, 1837, the theme and plot were taken from Danish history, but the spirit of his poems was distinctly southern. As a satirist and comic poet he followed Baggesen, and in all branches of the poetic art stood a little aside out of the main current of romanticism. In his best pieces, at the same time, he is the most modern and most cosmopolitan of the Danish writers of his time.

It is noticeable that all the great poets of the romantic period lived to an advanced age. Of the ten writers last considered, five died at an age of more than eighty, and the briefest life lasted to the confines of seventy years. This prolonged literary activity—for some of them, like Grundtvig, were busy to the last—had a slightly damping influence on their younger contemporaries, and since their day fewer great names have arisen. Four poets of the next generation, however, deserve most honourable mention.

Hans Christian Andersen (1805-1875), the greatest of modern fabulists, was born in very humble circumstances at Odense in Funen. His life was a struggle for existence, in the course of which he suddenly found himself famous. He attempted lyrical and dramatic poetry, novels, and travels, before he discovered the true bent of his genius. In all these branches of literature he escaped failure, but without attaining brilliant success. In 1835 there appeared the first collection of his *Fairy Tales*, and won him a world-wide reputation. Almost every year from this time forward until near his death he published about Christmas time one or two of these unique stories, so delicate in their humour and pathos, and so masterly in their simplicity. He also wrote, later in life, some excellent novels, *The Two Baronesses*, *Only a Player*, and others; his early story of *The Improvisatore*, 1835, has also considerable charm. Andersen was an incessant wanderer over Europe, and the impressions of his travels form a series of interesting, if egotistical, memoirs.

Carl Christian Bagger (1807-1846) published volumes in 1834 and 1836 which gave promise of a great future,—a promise broken by his early death. Frederik Paludan-Müller (1809-1876) survived much longer, and slowly developed a magnificent poetical career. He is one of the greatest names of Danish literature. His mythological dramas, his great satiric epos of *Adam Homo* (1841-48), his comedies, his lyrics, and above all his noble philosophic tragedy of *Kalanus*, prove the immense breadth of his compass, and the inexhaustible riches of his imagination.

The poets completely ruled the literature of Denmark during this period. There were, however, some eminent men in other departments of letters, and especially in philology. Rasmus Christian Rask (1787-1832) was one of the most original and gifted linguists of his age. His grammars of Old Frisian, Icelandic, and Anglo-Saxon were unapproached in his own time, and are still admirable. Niels Matthias Petersen (1791-1862), a disciple of Rask, was the author of an admirable *History of Denmark in the Heathen Antiquity*, and the translator of many of the Sagas. Christian Molbech (1783-1859) was a laborious lexicographer, author of the first good Danish dictionary, published in 1833. In Joachim Frederik Schouw (1789-1852), Denmark produced a very eminent botanist, author of an exhaustive *Geography of Plants*. In later years he threw himself with zeal into politics. His botanical researches were carried on by

Frederik Liebmann (1813-1856). The most famous zoologist contemporary with these men was Salomon Dreier (1813-1842.)

The romanticists found their philosopher in a most remarkable man, Søren Aaby Kierkegaard (1813-1855), one of the most subtle thinkers of Scandinavia, and the author of some brilliant philosophical and polemical works. A learned philosophical writer, not to be compared, however, for genius or originality to Kierkegaard, was Frederik Christian Sibbern (1785-1875).

Of novelists who were not also poets, only one was great enough to demand notice,—Andreas Nikolai de Saint-Anbain (1798-1865), who, under the pseudonym of Carl Bernhard, wrote a series of charming romances. We close our brief sketch of the romantic period with the mention of two dramatists, Peter Thun Foersom (1777-1817), who produced an excellent translation of Shakespeare, 1807-1816, and Thomas Overskou (1798-1873), author of a long series of successful comedies.

Latest Period.—Three living writers connect the age of romanticism with the literature of to-day. Parnio Carl Ploug (born 1813) is a vigorous politician and poet, violently Pan-Scandinavian, and editor of the newspaper *Fædelandet*. Meyer Aron Goldschmidt (born 1818) the life-long opponent of Ploug in politics and journalism, is the author of some novels written in the purest Danish, and with great vivacity and art. Jens Christian Hostrup (born 1818) is by far the best of the younger dramatists, having produced between 1843 and 1855 a series of exquisite comedies, unrivalled in delicacy and wit.

Hans Vilhelm Kaalund (born 1818) is a lyricist of much sweetness and force. He has lately published a good tragedy, *Fulvia*. Erik Bøgh (born 1822) is the author of inimitable songs, vaudevilles, and jeux d'esprit. Christian Richardt (born 1831) is the man of most decided genius among the younger poets. His four volumes of lyrical poems include some exquisite and many admirable pieces. Holgar Drachmann (born 1847) is a young poet, novelist, and painter of amazing fecundity, and great, though still uncertain, promise.

The greatest living Danish zoologist is Johannes Japetus Smith Steenstrup (born 1813). Jens Jakob Armussen Worsaae (born 1821) is an eminent antiquarian. Johan Nikolai Madvig (born 1804) is celebrated as a philologist, and particularly as one of the most eminent of modern Latinists. A young disciple of Madvig, Vilhelm Thomsen, has distinguished himself by his researches into the Slavonic languages. Rasmus Nielsen (born 1809) and Hans Brøchner (born 1820) are the two most eminent philosophers who have proceeded from the school of Kierkegaard. In æsthetic criticism no recent writer has approached—in knowledge, catholicity, and eloquence—Georg Brandes (born 1842), who stands alone among the writers of his country as an advocate for the most liberal culture and the most advanced speculation.

Fine Arts.—Within the present century the fine arts have been successfully cultivated in Denmark. In painting there has been displayed of late years an increased power and variety. The father of Danish painting, Nikolaj Abildgaard (1744-1809), was a man of great but rhetorical talent, taught in the French school of his day. Jens Juel (1745-1802), a portrait-painter of the same age, is a great favourite among the Danes. It was, however, Eckersberg (1783-1853) who gave the first real stimulus to the art of the nation. He was the pupil, first of Abildgaard, afterwards of David in Paris. In a distant and imperfect way he may be said to hold a position analogous to that of Turner in England. The influence of this genius has not been entirely beneficial, and while the Danish painters reproduce what they see around them with photo-

At length, after a long life of vicissitudes, he was compelled to receive obligations from those whom he had been continually reviling. In the very close of his days a play was acted for his benefit at the little theatre in the Haymarket, through the united interests of Thomson, Mallet, and Pope. It is much to the credit of Pope especially that, notwithstanding the gross manner in which Dennis had calumniated him on many occasions, he took part in the arrangements, and even wrote an occasional prologue to the play, which was spoken by Cibber. Not long after this Dennis died, on the 6th of January 1734.

DENON, DOMINIQUE VIVANT, BARON DE (1747–1825), artist and archæologist, was born at Châlon-sur-Saône on the 4th January 1747. His parents sent him to Paris to study law, but he showed from the first a decided preference for art and polite literature, and he soon gave up his professional studies. In his twenty-third year he produced a comedy, *Le bon père*, which obtained a *succès d'estime*, its author having already made himself a favourite in society by his agreeable manners and exceptional conversational powers. He brought himself under the notice of Louis XV. with such address as to establish at once his position in court favour. The king intrusted him with the collection and arrangement of a cabinet of medals and antique gems for Madame de Pompadour, and subsequently appointed him attaché to the French embassy at St Petersburg. On the accession of Louis XVI. Denon was transferred to Sweden; but he returned, after a brief interval, to Paris with the ambassador M. de Vergennes, who had been appointed foreign minister. In 1775 Denon was sent on a special mission to Switzerland, and availed himself of the opportunity to visit Voltaire at Ferney. He took a portrait of the philosopher, which was engraved and published on his return to Paris. His next diplomatic appointment was to Naples, where he spent seven years, first as secretary to the embassy and afterwards as *chargé d'affaires*. He devoted this period to a careful study of the monuments of ancient art, collecting many specimens and making drawings of others. He also perfected himself in etching and mezzotinto engraving. The death of his patron, M. de Vergennes, in 1787, led to his recall, and the rest of his life was given mainly to artistic pursuits. On his return to Paris he was admitted a member of the Academy of Painting. After a brief interval he returned to Italy, and resided for some years chiefly at Venice. He also visited Florence and Bologna, and afterwards went to Switzerland. While there he heard that his property had been confiscated, and his name placed on the list of the proscribed, and with characteristic courage he resolved at once to return to Paris. His situation was critical, but he found support and protection in the friendship of the painter David, who obtained for him a commission to furnish designs for republican costumes. This he did to the satisfaction of the Revolutionists, and his name was removed from the list of emigrants. When the terrors of the Revolution were over, Denon was one of the numerous band of eminent men who found a congenial resort in the house of Madame de Beanharnais. Here he formed the acquaintance of Bonaparte, to whose fortunes he attached himself with the happy instinct of one who was always quick to discern the coming power. On the special invitation of the general he joined the expedition to Egypt, and thus found the opportunity of gathering the materials for his most important literary and artistic work. He accompanied General Desaix to Upper Egypt, and made numerous sketches of the monuments of ancient art, sometimes under the very fire of the enemy. The results were published in his *Voyage dans la basse et la haute Egypte* (2 vols. fol., with 141 plates, Paris, 1802), a work which crowned his reputation both as an archæologist and as an

artist. In 1804 he was appointed by Napoleon to the important office of director-general of museums, which he filled greatly to the benefit of art and artists until the restoration in 1815, when he had to retire. He was a devoted friend of Napoleon, whom he accompanied in his expeditions to Austria, Spain, and Poland, taking sketches with his wonted fearlessness on the various battle-fields, and guiding the conqueror in his choice of spoils of art from the various cities that were pillaged. After his retirement he occupied himself with the preparation of a profusely illustrated history of ancient and modern art, in which he had the co-operation of several skilful engravers. He died at Paris on the 27th April 1825, leaving the work unfinished. It was published posthumously, with an explanatory text by Amaury Duval under the title *Monuments des Arts du dessin chez les peuples tant anciens que modernes, recueillis par Vivant Denon* (4 vols. fol. Paris, 1829).

DENTISTRY. The province of dentistry embraces the art of treating diseases and lesions of teeth, and supplying artificial substitutes in the place of these organs when lost. Disease of the teeth is not always a mere local affection, but may, and very generally does, arise from constitutional causes. With cases of the latter description the dentist, unless qualified as a surgeon or physician, is not in a position to deal, except in so far as to repair or ameliorate the local affections produced. The morbid conditions of the system leading in some way to disorders of the dental tissues are various and dissimilar in their nature; and the exact connection between such morbid conditions and their effects upon the teeth is not well understood. In this way the diagnosis, the treatment, and the removal of the cause might be considered more properly the duty of the general practitioner than of the specialist. Up to a very recent date this has been more particularly the case, dentists until lately having in the greater number of instances been educated with a view to proficiency in the mechanical rather than the surgical department of their profession, while what surgical knowledge they, in a few cases, did acquire was confined to certain facts connected exclusively with the organs upon which they were expected to operate. From the *Lancet* for 3d June 1876 it appears that not much more than fifty of all the numerous body of so-called surgeon-dentists of the United Kingdom then possessed in reality any medical or surgical diploma at all.¹

¹ Indeed it is comparatively of late years that dentistry has occupied anything like a properly recognized position among the different departments of minor surgery; for long it was practised to a large extent as a superadded means of livelihood by persons engaged in some other pursuit, and without any professional education whatever. The blacksmith, barber, watchmaker, and others of the same class were the dentists of every village and country town; while even in some of our larger cities dentists of the kind were till lately to be found practising under the very shadow of universities and medical schools. The explanation of this seems to have been that mere tooth-drawing constituted the surgical dentistry of these days, and as the operation is one demanding muscular strength and manual dexterity more than anatomical knowledge or surgical skill, and was performed as successfully in many cases by the irregular as by the regular practitioners, it had not many attractions for medical men. It was accordingly consigned to the uneducated and the charlatan, who did not fail with proverbial unscrupulousness to parade their speciality as sufficient to confer a surgical status on those performing it, and entitle them to the designation of *surgeon dentist*,—a designation which has ever since been applied without discrimination or distinction to qualified or unqualified practitioners in this particular branch. In 1840 or 1841 this state of matters seems to have attracted the attention of the profession, since, after much consideration, some anxiety was manifested by its more respectable members to be recognized in the new Medical Act of 1843, then being introduced by Sir James Graham. Both then and later, however, the fully qualified medical men objected to the fractionally qualified being made to appear as on an equal footing with themselves. The profession may at this time be said to have divided itself into three sections—1st, those who desired to see all dentists fully qualified surgeons; 2d, those who wished them to have only a certain amount of surgical knowledge,

by extraction such teeth as are in the way, and by mechanical contrivances, known as regulating plates, to apply pressure in such a manner as will move the misplaced tooth or teeth into their normal position, and retain them there for some time afterwards. Such plates are constructed on the same principles, and of the same materials, as the bases of artificial sets, which will come to be treated of afterwards. It not unfrequently happens that nature, if left to herself, effects a wonderful improvement in cases of dental irregularity. This is frequently observable where it is the upper canines which are misplaced. These teeth when appearing, as they often do, outside and much above the necks of the adjoining teeth, occupy a long time in descending, and in certain cases the anterior portion of the maxillary arch seems to enlarge sufficiently to afford space for their almost perfect arrangement during this period. The same thing occurs, but to a less marked extent, in the case of other teeth; in general, however, nature requires to be assisted by art in some way, as has been above indicated, where the irregularity exists to any great amount.

Diseases of Teeth.—The teeth being living organisms are, like other structures in the animal body, subject to disease. Some of the diseases bear a close resemblance to mere chemical decomposition, such as occurs in dead or inorganic matter, and at a certain stage of some dental affections a process of the kind does no doubt occur; but this is so mixed up with, and accompanied and preceded by vital action, that to consider it as a mere chemical or physical lesion would be pathologically incorrect. Various arguments have been advanced by its advocates in support of the chemical theory of dental caries; but however ingenious or specious these at first sight appear, they fail to explain many phenomena in the origin, the period of occurrence, and the stages and progress of this disease, unless the vital element in its nature be also taken into account.

Dental caries, or decay of the teeth, may briefly be described as consisting in a previous imperfect development, or in the access of some morbid action interfering with the nutrition or vitality of their tissues, thus rendering them liable to any destructive agencies to which they may be subjected, by which they become disorganized, disintegrated, and broken down, leaving the sensitive pulp exposed, whereby acute pain is occasioned, especially when the destruction of the protective tooth substance has been rapid. Sometimes the process of decay is insidious and unobserved. Its advent is then supposed to have been sudden, and its progress more speedy than has really been the case. This, however, in many instances arises from the condition of matters being overlooked until the enamel, which resists destruction longest, being undermined and falling in, reveals for the first time the cavity existing underneath. Pain, probably also for the first time, is then experienced from exposure and irritation of the dentinal pulp, and toothache, as it is termed, is produced.

Necrosis, or death of a whole tooth, is another lesion to which these organs are liable. This may result from either acute or chronic inflammation in the tissues connecting them with the jaw, or from a blow, or from any other cause leading to their vascular supply being cut off. The necrosis may involve the whole tooth, or it may be partial—as, for example, where it is limited to one fang of a multiple fanged tooth. In these cases there may be no breaking down of texture, but the tooth becomes discoloured, loosened, extruded, and at last detached from its socket, from which after a time, and generally after considerable uneasiness, it drops out.

Exostosis, or a morbidly increased growth of certain parts of a tooth, being in almost every instance confined to the cement substance described as covering the fang or root, is an affection somewhat obscure in its outward

symptoms. It is generally a consequence of previous disease of the tooth, leading to chronic inflammation of the textures covering the fang and lining the socket (or alveolus) in which it is implanted. This leads to a deposition of new material in the cement till that substance appears in nodular masses attached to or surrounding the apex of each fang, and sometimes uniting several of such fangs into one. The presence of this additional and increasing bulk of hard tissue within the inclosing socket produces pain of a severe and somewhat anomalous character by pressure on the adjacent nerves, which is often mistaken for neuralgia or tic of a less unaccountable origin. It further acts within the unyielding bony socket referred to as a means of rendering removal of the tooth much more difficult, owing to the bulbous extremity of the enlarged fang acting like a rivet in its fixation. Generally, however, the teeth in which exostosis occurs have been too long the subjects of irritation and decay not to be suspected when obscure pain of a less localized nature exists in their vicinity; and not unfrequently there is found round the necks of teeth or stumps so affected a red and tumid condition of the gum, sufficiently indicative of the state of matters below to warrant their extraction.

Alveolar abscess, or gum boil, as it is popularly denominated, is a localized inflammation going on to suppuration, and generally confined to the tissues surrounding the apex of a tooth fang. The pain usually commences with a feeling of tenderness and enlargement or lengthening of the whole tooth. The gum becomes swollen and tender over the whole depth of the root, generally to a greater extent on the outer side of the jaw. The face also becomes swollen, and the glands in the neighbourhood of the jaw feel enlarged and tender. The pain is not commonly continuous, but rather remitting in its character, sometimes ceasing altogether—only, however, to be followed by an increased attack, while its repeated exacerbations night and day lead in many cases to very considerable constitutional disturbance. After a time the purulent matter secreted makes its way to the surface, sometimes finding an escape alongside of or through the pulp cavity of the fang, and very frequently, as the name given to the disease indicates, by pointing and discharging itself through the gum.

Occasionally, instead of pointing on the surface of the gum, the matter takes a more indirect course and points on the surface of the cheek, bursting and leaving an open sore there which seldom closes until the tooth or stump has been extracted. At an early stage of this disease fomentations and other modes of relieving inflammatory action do good, but evacuating the matter by means of incisions or extraction of the offending tooth are the only reliable remedies at a later period.

Teething.—What is termed dentition, although in its widest sense properly including the development of the teeth within, as well as their subsequent appearance through, the superimposed tissues, is generally restricted in its application to the latter division of this process, more especially as it occurs in connection with the temporary or milk set, during the period of early infancy. The genesis, increment, and evolution of these organs involve so much of what is purely physiological, and would entail the discussion of so many points of a histological nature, that only the latter stages of evolution or cutting of the teeth can be referred to here. Regarding this occurrence, the most vague and contradictory opinions have been entertained. Erroneous notions of its nature, and of the exact manner in which to account for many of its phenomena, have been and still are promulgated. A number of morbid affections incident during infancy are set down as clearly attributable to the tooth's penetration of its inclosing tissues, and considered by many authorities as of every day

occurrence; while the views advanced with reference to the pathology and treatment of such cases, suppositional or otherwise, are equally various and conflicting. The probable solution of the difficulty seems to be that, while evil consequences may in certain instances be traceable to dentition, the frequency and importance of such cases is very much exaggerated.

Extraction.—This constitutes the most important operation of a surgical nature falling under the care of the dentist, and is chiefly called for where the condition of the tooth, from disease or injury, precludes the possibility of saving it by stopping or other means. The operation is also frequently resorted to where the teeth are too crowded in the jaw, or where they are irretrievably misplaced, or where supernumerary members of the series exist and occasion inconvenience. In order to extract any tooth successfully, there is demanded a knowledge of what its configuration normally ought to be, and of the proper instrument to use; and, along with these, the condition to which decay or other disease may have reduced the tooth must be kept in mind while proceeding with the operation.

In seizing a tooth in order to its extraction the part upon which the hold is taken should be sufficiently sound and strong to withstand the force necessary for dislodging the fangs; and to obtain such a hold it is necessary to thrust the grasp of the instrument as far as possible beyond the spot affected by decay. It should then be detached from the walls of its socket in that direction where least resistance is likely to be met. This must be judged of according to circumstances, but in general is indicated by an acquaintance with the anatomy of the structures concerned. After being thus loosened it has merely to be lifted from the jaw to complete the operation. Sometimes a tooth is so firmly secured in the jaw that its own tissue will give way before it will separate from the alveolar cavity in which it is fixed. This is particularly the case in friable teeth; and frequently even in the strongest teeth the root or fangs may be malformed or bent, or secured in such a manner as renders their extraction extremely difficult or altogether impossible by any ordinary means.

The instruments employed in extraction may be divided into those which grasp the tooth between their blades and literally extract or draw it out, such as forceps, and those which apply the dislodging force by acting as a lever in the manner of a crow bar, such instruments being termed elevators. The key, an instrument of great power, but now very properly almost disused, partakes in a measure of the properties of both these instruments, but that in a very imperfect and disadvantageous manner. In some rare cases, however, it may be found of much service when used with circumspection. It is impossible here to enter into detail regarding the different forms of forceps, elevators, and other instruments required in dental surgery; but one great principle may be laid down with respect to all of them, which applies especially to forceps, and that is that their form should be as simple as possible consistently with fitting and grasping securely the particular tooth they are intended to remove, and with conveniently reaching that part of the mouth in which it is situated.

Regulation of Teeth.—In the extraction of teeth for the purpose of affording space in cases of dental irregularity from overcrowding, it often becomes necessary to remove a healthy organ, and before doing so among the permanent teeth certain questions present themselves for consideration. Unless there be a fair probability of such a step being successful it endangers the loss of two teeth should the originally misplaced one be so objectionable and so unyielding to treatment as to require this. In the temporary set the principal disadvantage connected with the removal of

any of their number is when to make room for one permanent tooth two or more temporary ones would require extraction,—as of course space is thus provided at the expense of the second permanent tooth, for which one of the two temporary ones was keeping a place. In this set, however, the objection to removal of any of its series is greatly obviated by the fact that, while the teeth are very soon to be lost at all events, the jaw is increasing in size and progressively affording more and more room itself for the incoming second set. Along with extraction, in the great majority of instances pressure requires to be applied to the misplaced teeth in order to effect their regulation. This has generally to be continuously kept up for a considerable period, and in many cases requires to be maintained after the teeth have been restored to their natural position in order to keep them there until they seem settled in the new locality. Various forms of what are called regulating plates are used for the purpose of applying pressure in this manner, and may be said generally to consist of a framework fitted and fixed to the adjoining teeth something in the same manner as an artificial set, and calculated to afford a fixed point or fulcrum from which to act on the tooth to be moved.

In disease of the dental tissues it is not always necessary to remove the affected organ; such an extreme measure as this is only called for when other remedial means have failed, or appear hopeless. The chief of all dental diseases demanding the dentist's care is, as has been already stated, that known as caries, or decay. It is this affection directly or indirectly that leads to by far the larger number of extractions performed, but it by no means follows that extraction is the only remedy at our command. Many teeth are extracted which might be saved, and the principal method by which this can be effected is by what is termed stopping, or plugging, or filling the teeth.

Stopping.—The operation of stopping a decayed tooth consists in cleaning out the carious cavity and removing all the softened or disintegrated tissue, and shaping and trimming it so as to reduce it to a form fit for receiving and retaining the material with which it is to be filled up. Along with these proceedings it in general becomes necessary to diminish the sensitive condition in which the interior surface of the prepared cavity is left, to remove or destroy any of the vascular and highly nervous pulp which may be protruding into it, and to subdue any inflammation and arrest any discharge which may have been going on in the fang. Various applications and other remedial measures are resorted to for these purposes, the most common being the applying for a time some of the more convenient escharotics on a plug inserted into and left within the cleaned-out cavity till this end is achieved. When thus prepared, the cavity is ready to be filled with whatever substance has been selected to replace the lost tissue, and as nearly as possible to restore the contour of the tooth. The substances employed as permanent stoppings are generally metallic. Gold in the form of foil, or in that condition known as sponge gold, tin in the form of foil, and amalgams, composed of various metals either in a simple or compound condition combined with mercury, are the principal materials in use as stoppings. The oxyphosphides, from their being capable of insertion in a plastic state, and quickly acquiring a density and hardness approaching that of tooth bone, are also favourites with many as serviceable fillings; and various preparations of gutta-percha, gum resins, sulphur, and other matters have long been known as valuable, though not very durable, when employed in certain cases.

Dexterity in the insertion of a gold or other foil filling is a matter which can be acquired by experience alone. The general principles are that, the cavity being prepared and

shaped as already described, the gold plug should be secured and consolidated piece by piece, until there is built up a mass filling every part of the vacant space with a uniform consistency of metal which, when finished, ought to present the feeling of being as hard as a piece of solid gold.

The other fillings are more easily dealt with. The same careful preparatory steps are requisite in all fillings, but the insertion of the plug in amalgam and other stoppings being performed while the material is in a plastic condition, the process is rendered much more simple. The cavity should be completely filled, but not over-filled, and the amalgams ought to be used with as little mercury as is at all possible. A number of instruments are necessary for effecting all these various manipulations, but to describe them here would be as unintelligible as it appears unnecessary. Excavators, enamel cutters, burr head drills, points, pluggers, burnishers, &c., are only some of those required, while their modes of use are either by the hand or by mechanical-apparatus, such as what are termed burring-engines, &c. Stopping may be regarded as one of the most valuable operations in modern dentistry; and although it is no guarantee that the tooth stopped is ever after safe from the renewed attack of caries any more than its unstopped neighbours are from its original attack, yet it is surprising how few well-filled teeth are lost by caries recommencing in the stopped cavity.

Besides those already mentioned, the teeth and jaws are subject to a number of disorders and lesions which it would be out of place here to do more than enumerate. Fracture and dislocation of the teeth, ulceration and absorption of the gum, necrosis and exfoliation of the jaw, alteration in the secretions of the mouth, the deposit of tartar or salivary calculus on the teeth or in the salivary ducts, the effect of various medicines and poisonous agents on the teeth, jaws, and mouth generally,—these and the like matters are all of much interest, and more or less connected with dentistry proper. But for information in regard to them the reader must be referred to the various excellent publications treating of them, which have appeared in considerable numbers since dental surgery has occupied more notice and taken a place as one of the recognized specialities of medicine.

Mechanical dentistry, properly so called, consists in the construction of artificial substitutes to supply the place of lost teeth. Stopping and such like operations might also be classed with mechanical dentistry as contrasted with purely surgical treatment, as yet, however, these matters are not quite decided; and the day when the dental surgeon and the mechanical dentist—like the ophthalmic surgeon and the optician—should each occupy a separate sphere has not arrived. All that can here be given is a mere outline of the principles involved in mechanical dentistry. The subject is one comprehending a knowledge of many departments of mechanical science, and to do more than indicate the nature of the various modes of construction, and the processes carried on in the manufacture of artificial teeth, would be useless and inexpedient.

The removal of roots and stumps as a preparatory step in the fitting of artificial teeth is a matter to be decided by the circumstances of the case. The length of time which can be afforded for cicatrization and absorption of the alveolar walls and gum; the presence of adjoining teeth to be left standing, especially front teeth, the fitness of the patient for the operation of extraction,—these and other circumstances must determine what amount of surgical preparation is to precede the supplying of false teeth. As a general rule, the clearer the gums are of stumps and decayed teeth the better, but at the same time certain advantages, transitory as they may be, are in some instances to be derived from their retention.

The jaw, gum, and teeth being then considered as in a suitable condition, the first step in the process is to obtain a plaster cast of the parts,—“the model,” as it is termed. This is done by pressing softened beeswax or some similarly plastic composition against them until they are imbedded and leave an impression in it, giving an exact mould of the gums, remaining teeth, and all other parts on its removal. Plaster of Paris is now run into the mould so obtained, and when this is set and hardened a perfect facsimile of the structures to be fitted is the result.

Any further proceedings now depend upon the mode and material in which the future artificial set is to be constructed. Every set of artificial teeth consists of representatives of the lost organs, modelled in a species of porcelain, and mounted upon a base adjusted to the gum and remaining natural teeth. This base is manufactured in a variety of materials, the principal of which are—(1) metal plate, of gold, platinum, silver, or different alloys, (2) vulcanized caoutchouc, or vulcanite, as it is called, and (3) celluloid base, a composition of collodion and camphor, which has not been long enough tested as yet to rank with the other substances; while (4) the teeth may be mounted merely with as much extraneous material as will support a pin or pivot by which they may be attached as new crowns to a root in which such pivot is firmly inserted. When it is intended that the base shall be of gold or other plate, a metal die and counter have to be made from the plaster model, between which dies the plate is embossed, and the requisite form obtained. The die and counter die are generally made the one in zinc or gun metal, the other in lead or tin; and—unlike the dies from which jewellery patterns, &c., are embossed, and which may serve for thousands of times—the dental dies, having served to emboss the plate for one patient, are of no further use for any other case. The plate being thus far advanced next requires to be adjusted to the mode in which the patient closes the opposing jaw or teeth against it in shutting the mouth—in other words, the “bite” has to be taken, and the artificial teeth, which are to be mounted on the plate, arranged accordingly. Any fastenings supporting or steadying the set have also to be adjusted, and after this, if everything has gone well, the false set should be ready for placing in its destined locality and for use by the wearer.

Should it be proposed to make the base of vulcanite, celluloid base, or a similar material, a different mode of procedure must be adopted. These materials necessitate a greater bulk of substance occupying the mouth than is the case where metal plate is employed. This, however, is in some cases an advantage—since, for instance, where the gum has been greatly diminished in size through absorption, it requires some bulk of material to restore the parts to their normal size, and to give the former natural expression to the features. In preparing a vulcanite base no metal die is necessary. The base is built up in wax directly on the plaster model, and the porcelain teeth adjusted in their places, the bite and attachments being carefully attended to, as described in speaking of plate cases. The set thus made up, and presenting the exact counterpart of what the finished work is intended to be, is now, after testing it and finding it correct and perfect in the mouth, imbedded in Paris plaster as follows. A small box, or “flask,” as it is denominated, of iron or other metal, like one saucer inverted on the top of another, is opened and the model with the wax-built set on it is placed in the lower saucer, which is then filled up with plaster to the level of the wax set. This being allowed to harden is soaped or oiled all over its surface, and the lid of the flask, or what corresponds to the upper saucer, is now placed upon the under portion of the flask. An opening in this covering portion enables plaster to be next poured into it till the inclosed

wax-mounted set is shut up like a fossil in the heart of its stony covering. On the two halves of the flask being separated, the set of course remains firmly secured in the lower portion. Boiling water is now poured over it, and the wax thus melted out, leaving the porcelain teeth undisturbed and *in situ*. A cavity is thus left when the two sides of the flask are again closed, representing exactly the form of the wax removed. Raw vulcanite, or whatever other material of the kind is to be used, is now introduced with care into the space thus left by the removal of the wax. The two sides of the flask are next brought together and maintained there by the pressure of a clamp and screw. The whole is then placed in a vessel termed a vulcanizer, where it is subjected, for the space of from an hour and a quarter to two hours or more, to the action of steam at a temperature ranging up to 320° Fahr., at the end of which time the piece will be found hard and ready for finishing and polishing as may be desirable. In firing and manipulating the celluloid base some modification of this process is required, but as yet the substance is comparatively little used, and would scarcely justify further remark in this place.

What is termed a pivot tooth, again, is an artificial tooth having a metal or sometimes a wooden pin firmly attached to it; and this being inserted into the opened pulp cavity of a healthy fang, the artificial forms a secure and very perfect substitute for the original crown when destroyed by caries, broken off, or otherwise lost.

The use of artificial teeth, especially by those previously unaccustomed to them, requires considerable practice and no small amount of perseverance. The larger the artificial set—that is, the greater the number of teeth replaced,—the greater the difficulties and the more the discomfort experienced. Time, however, works wonders here as in many other instances. It is not an uncommon thing to find a set which never has fitted well, or one which owing to many years of use does not fit well, being felt so comfortable, through mere habit of wearing it, that on a new and perfectly fitting set being made, the old one, with all its faults, is preferred to the other. A few days' wear, however, of the new one generally brings all the shortcomings of the old glaringly out on its being again attempted to be worn. And in the same manner, a week or two's perseverance generally enables any ordinary set to be worn and used with comfort and facility even by patients who are for the first time under the dentist's care. Various modes of fixation are adopted for the retaining of artificial teeth in their proper situation. Atmospheric pressure, or "suction," as it is termed, is the simplest of all, being merely the hold established between the palate and the set in the same way as occurs between a wet leather "sucker" and the stone it lifts. Another method is by what are termed "spiral springs," a mode only applicable, however, where both an upper and lower set are worn at the same time. And a third style of fixation is where the set is supported upon certain natural teeth among those remaining in the patient's jaw. Each mode has its own advantages, and sometimes one or other method is the only one at all possible to be adopted. This, however, is seldom a difficult matter to decide by any one who has had much experience of either the operating room or the dental workshop.

The art of dentistry is difficult to acquire, and comprehends in itself processes appertaining to several separate branches of manufacture. It is, however, an art which is an extremely useful one, and has done valuable service, since it is not too much to say that in all probability many lives have been saved and a still greater number prolonged through the instrumentality of the aid afforded by the use of artificial teeth.

Literature of the subject and authorities on Dental Surgery—Gardner, *Edinburgh Medical Journal*, 1838; Heaton, *On Diseases of the Jaw*, 1858; Owen, *On the Skeleton and Teeth*, 1855; Tome's *Dental Surgery*, 1873; Taft's *Operative Dentistry*, 1877; Sailer's *Dental Pathology*, 1874; Smith's *Dental Anatomy and Surgery*, 1854, and various papers in *Edinburgh Medical Journal*, *Proceedings of Royal Society of Edinburgh*, &c., from 1852; Cole's *Dental Mechanic*, 1876; Waldeyer, in *Stricker's Handbuch*, 1876; Turner's *Human Anatomy*, 1877; Richardson's *Mechanical Dentistry*, 1869; Wedd's *Pathology of the Teeth*, 1869; various papers, by Kolmer, Arnold, Boll, Robt and Magator, Huxley, &c., in British and Continental journals. (1, 2, 3)

DENVER, a city of the United States of America, capital of the State of Colorado, and of Arapahoe county, occupies a commanding position on the south bank of the South Platte river, where it is joined by the Cherry creek, 500 miles west of the Missouri,—its elevation above the level of the sea being 5267 feet. The town, which is of recent origin, and mostly built of brick, contains some large public buildings connected with the State administration, as well as a large public school, a State library, and churches belonging to the different denominations. It forms the centre of an important railway system, and has several factories engaged in smelting, iron founding, and wood work, besides a mint for assaying gold and silver ore, breweries, wool mills, &c. The population, which numbered 4759 in 1879, and was estimated at 15,000 in 1873, is rapidly increasing.

DEODAND (*Deo dandum*), in English law, was a personal chattel (any animal or thing) which, on account of its having caused the death of a human being, was forfeited to the king for pious uses. Blackstone, while tracing in the custom an expiatory design, alludes to analogous Jewish and Greek laws,¹ which required that that what occasions a man's death should be destroyed. In such usages the notion of the punishment of an animal or thing, or of its being morally affected from having caused the death of a man, seems to be implied. The forfeiture of the offending instrument in no way depends on the guilt of the owner. The imputation of guilt to inanimate objects or to the lower animals, repugnant as it is to our habits of thought, is not inconsistent with what we know of the ideas of uncivilized races. In English law, deodands came to be regarded as mere forfeitures to the king, and the rules on which they depended were not easily explained by any key in the possession of the old commentators. The law distinguished, for instance, between a thing in motion and a thing standing still. If a horse or other animal in motion killed a person, whether infant or adult, or if a cart run over him, it was forfeited as a deodand. On the other hand, if death were caused by falling from a cart or a horse at rest, the law made the chattel a deodand if the person killed were an adult, but not if he were a person below the years of discretion. Blackstone accounts for the greater severity against things in motion by saying that in such cases the owner is more usually at fault, an explanation which is doubtful in point of fact, and would certainly not account for other instances of the same tendency. Thus, where a man's death is caused by a thing not in motion, that part only which is the immediate cause is forfeited, as "if a man be climbing up the wheel of a cart, and is killed by falling from it, the wheel alone is a deodand;" whereas, if the cart were in motion, not only the wheel but all that moves along with it (as the cart and the loadings) are forfeited. A similar distinction is to be found in Britton. Where a man is killed by a vessel at rest the cargo is not deodand; where the vessel is under sail, hull and cargo are both deodand. For the distinction between the death of a child and the death of an adult Blackstone accounts by suggesting that the child "was presumed incapable of

¹ Compare also the rule of the Twelve Tables, by which an animal which had inflicted mischief might be surrendered in lieu of compensation.

actual sin, and therefore needed no deodand to purchase propitiatory masses; but every adult who died in actual sin stood in need of such atonement, according to the humane superstition of the founders of the English law." Sir Matthew Hale's explanation was that the child could not take care of himself, whereon Blackstone asks why the owner should save his forfeiture on account of the imbecility of the child, which ought to have been an additional reason for caution. The finding of a jury was necessary to constitute a deodand, and the investigation of the value of the instrument by which death was caused occupies an important place among the provisions of our early criminal law. It became a necessary part of an indictment to state the nature and value of the weapon employed—as, that the stroke was given by a certain penknife, of the value of sixpence—so that the king might have his deodand. Accidents on the high seas did not cause forfeiture, being beyond the domain of the common law; but it would appear that in the case of ships in fresh water, the law as quoted above from Britton held good. The king might grant his right to deodands to another.

In later times these forfeitures, so unintelligible in their purpose, so capricious and unjust in operation, became extremely unpopular; and juries, with the connivance of judges, found deodands of trifling value, so as to defeat the inequitable claim. But deodands were not abolished till the 9 and 10 Vict. c. 62 was passed, whereby it is enacted that "there shall be no forfeiture of any chattel for or in respect of the same having caused the death of a man; and no coroner's jury sworn to inquire, upon the sight of any dead body, how the deceased came by his death, shall find any forfeiture of any chattel which may have moved to or caused the death of the deceased, or any deodand whatsoever; and it shall not be necessary in any indictment or inquisition for homicide to allege the value of the instrument which caused the death of the deceased, or to allege that the same was of no value." The date of this Act (1846) may suggest the great inconvenience which the law, if it had remained in operation, would have caused to railway and other enterprise in which loss of life is a frequent occurrence.

DEPRÈS, JOSQUIN (1440–1521), also called Desprez, and, by a Latinized form of his name, Jodocus Pratensis or a Prato, a celebrated musical composer, was born about 1440 at Vermand, near St Quentin, in French Flanders. He was a pupil of Ockenheim, the great contrapuntist, and himself one of the most learned musicians of his time. In spite of his great fame, the accounts of his life are vague and scanty, and even the place of his birth has only lately been established beyond dispute—Belgians, Germans, Italians, and Frenchmen claiming him as their countryman. M. Fétis, the well-known historian of music, has contributed greatly towards elucidating the doubtful points, and to that author's *Biographie Universelle* the reader is referred for more detailed information. In his early youth Josquin seems to have been a member of the choir of the collegiate church at St Quentin; when his voice changed he went (about 1455) to Ockenheim to take lessons in counterpoint, afterwards he again lived at his birth-place for some years, till Pope Sixtus IV. invited him to Rome to teach his art to the musicians of Italy, where musical knowledge at that time was at a low ebb. In Rome Deprès lived till the death of his protector (1484), and it was there that many of his works were written. His reputation grew rapidly, and he was considered by his contemporaries to be the greatest master of his age. Luther, himself an excellent musical amateur, is credited with the saying that "other musicians do with notes what they can, Josquin what he likes." The composer's journey to Rome is in itself a most important event in the history of musical progress; for it marks in a

manner the transference of the art from its Gallo-Belgian birth-place to Italy, which for the next two centuries remained the centre of the musical world. To the school of the Netherlands, of which Deprès and his pupils Arcadelt, Mouton, and others are the chief representatives, modern music owes its rise. But far more important than this school itself was its outgrowth and successor, the so-called Roman school, immortalized by the name of Palestrina. After leaving Rome Deprès went for a time to Ferrara, where the art-loving duke Hercules I. offered him a home, but before long he accepted an invitation of King Louis XII. of France to become the chief singer of the royal chapel. According to another account, he was for a time at least in the service of the emperor Maximilian I. The date of his death has by some writers been placed as early as 1501. But this is sufficiently disproved by the fact of one of his finest compositions, *A Duge (Déploration) for Five Voices*, being written to commemorate the death of his master Ockenheim, which took place after 1512. The real date of Josquin's decease has since been settled as the 27th August 1521. He was at that time a canon of the cathedral of Condé. The most complete list of Deprès's compositions—consisting of masses, motets, psalms and other pieces of sacred music—will be found in Fétis. The largest collection of his MS. works, containing no less than 20 masses, is in the possession of the Papal chapel in Rome. The well-known works by Drs Burney and Hawkins give specimens of his music.

DEPTFORD, a town of England situated at the junction of the Ravensbourne with the Thames, $3\frac{1}{2}$ miles east of London Bridge. It forms the western portion of the parliamentary borough of Greenwich, occupying an area of about 1650 acres, situated mostly in the county of Kent, and partly in Surrey. It comprises two parishes—that of St Nicholas, including Lower Deptford on the Thames, and St Paul's, or the landward part of the town, which extends into Surrey and includes Hatcham Manor. Lower Deptford consists of irregular narrow streets, and the houses are mostly of a mean description. It contains the site of the old dockyard, and the royal victualling yard is also situated there. The former was discontinued as a dockyard in 1869; it was filled up and converted into a foreign cattle market by the corporation of London, but this was given up in 1873. The victualling yard immediately to the west of it is the most important establishment of its kind in the kingdom, supplying the navy with provisions, medicines, furniture, &c, which are manufactured or stored in the large warehouses that constitute the establishment. As many as 500 hands are employed in the warehouses and at the lading wharf. The only other industrial employment of importance in the place is to be found in the engineering works, which are carried on near the river. Of public buildings the most noteworthy are St Nicholas Church, with a square embattled tower, built on the site of an older structure at the beginning of the last century, and St Paul's, of classic design, erected in 1730. There is also the hospital for master mariners, maintained by the corporation of the Trinity House, which was originated here. Of the mansion known as Sayes Court with which Deptford is historically identified, nothing now remains but the garden. The house—taken down in 1729—was the residence of the duke of Sussex in Queen Elizabeth's time; it was occupied in the following century by John Evelyn, the author of *Sylva*, and by Peter the Great during his residence in England in 1698. The population of Deptford in 1871 amounted to 60,188 persons, seven-eighths living in the landward parish of St Paul's.

DE QUINCEY, THOMAS (1785–1859), an eminent English author, was born at Greenhay, near Manchester,

on the 15th of August 1785. He was the fifth child in a family of eight (four sons and four daughters), of whom three died young. His father, descended from a Norman family, was an opulent merchant, who lived much abroad, partly to look after his foreign engagements, but mainly from considerations of health, he died of pulmonary consumption in the thirty-ninth year of his age, leaving his wife and six children a clear income of £1600 a year. The widow, a woman of exceptional talent, secured to her family the enjoyment of those social and educational advantages which their position and means afforded. Thomas was from infancy a shy, sensitive child, with a constitutional tendency to dreaming by night and by day, and, under the influence of an elder brother, a lad "whose genius for mischief amounted to inspiration," who died in his sixteenth year, he spent much of his boyhood in imaginary worlds of their own creating. The amusements and occupations of the whole family, indeed, seem to have been mainly intellectual, and in De Quincey's case, emphatically, "the child was father to the man." "My life has been," he affirms in the *Confessions*, "on the whole the life of a philosopher; from my birth I was made an intellectual creature, and intellectual in the highest sense my pursuits and pleasures have been." From boyhood he was more or less in contact with a polished circle; his education, easy to one of such native aptitude, was sedulously attended to. When he was in his twelfth year the family removed to Bath, where he was sent to the grammar school, at which he remained for about two years, and for a year more he attended another public school at Winkfield, Wiltshire. At both his proficiency was the marvel of his masters. At thirteen he wrote Greek with ease; at fifteen he not only composed Greek verses in lyric measures, but could converse in Greek fluently and without embarrassment, one of his masters said of him, "that boy could harangue an Athenian mob better than you or I could address an English one." Towards the close of his fifteenth year he visited Ireland, with a companion of his own age, Lord Westport, the son of Lord Altamont, an Irish peer, and spent there in residence and travel some months of the summer and autumn of the year 1800,—being a spectator at Dublin of "the final ratification of the bill which united Ireland to Great Britain." On his return to England, his mother having now settled at St John's Priory, a residence near Chester, De Quincey was sent to the Manchester grammar school, mainly that it might be easier for him to get thence to Oxford through his obtaining one of the school exhibitions.

Discontented with the mode in which his guardians conducted his education, and with some view apparently of forcing them to send him earlier to college, he left this school after less than a year's residence—ran away, in short, to his mother's house. There one of his guardians made an arrangement for him to have a weekly allowance, on which he might reside at some country place in Wales, and pursue his studies, presumably till he could go to college. From Wales, however, after brief trial, "suffering grievously from want of books," he went off as he had done from school, and hid himself from guardians and friends in the world of London. And now, as he says, commenced "that episode, or impassioned parenthesis of my life, which is comprehended in *The Confessions of an English Opium Eater*." This London episode extended over a year or more, at the end of it the lad was reconciled to his guardians, and in 1803 went to Oxford, being by this time about nineteen. It was in the course of his second year at Oxford that he first tasted opium,—having taken it to allay neuralgic pains.

After finishing his career of five years at college in 1808, he ultimately settled in 1812 to the life of a student on

the borders of Grasmere, drawn thither partly by neighbourhood to Wordsworth, whom he early appreciated,—having been, he says, the only man in all Europe who quoted Wordsworth so early as 1802. Here also he enjoyed the society and friendship of Coleridge, Wilson, and Southey, as in London he had of Charles Lamb and his select circle. Here he continued his classical and other studies, especially exploring the at that time almost unknown region of German literature, and indicating its riches to English readers. Here also, in 1816, he married the "dear M——," of whom a charming glimpse is accorded to the reader of the *Confessions*; his family came to be five sons and three daughters. For a year he edited, at Kendal, the *Westmoreland Gazette*. He resided till the end of 1820 at Grasmere, afterwards in London, and latterly at Lasswade near Edinburgh, or in Edinburgh. He died in that city December 8, 1859, aged seventy-four, and is buried in the West Churchyard.

During nearly fifty years De Quincey lived mainly by his pen. His patrimony seems never to have been entirely exhausted, and his habits and tastes were simple and inexpensive; but he was careless to recklessness in the use of money, and debts and pecuniary difficulties of all sorts hung about him through the greater part of his life. There was, indeed, his associates affirm, an element of romance even in his impecuniosity, as there was in everything about him; and the diplomatic and other devices by which he contrived to keep clear of clamant creditors, while scrupulously fulfilling many obligations, often disarmed animosity, and converted annoyance into amusement. The famous *Confessions of an English Opium Eater*, having first appeared in *The London Magazine*, were published in a small volume in 1820, and attracted a very remarkable degree of attention, not simply from their disclosures as to his excessive use of the drug, and its effects, but also by the marvellous beauty of the style of the work, its romantic episodes, and extraordinary power of dream-painting. All De Quincey's other writings appeared in periodicals—*Blackwood's Magazine*, *Tait's Magazine*, *Hogg's Instructor*, &c. No other literary man of his time, it has been remarked, achieved so high and universal a reputation from such merely fugitive efforts. Since his works were brought together, that reputation has been not merely maintained, but extended. The American edition of twelve volumes was reprinted in this country in 1853, under the author's own supervision, and expanded to fourteen volumes; upon his death two more volumes were made up of previously uncollected material. For range of thought and topic, within the limits of pure literature, no like amount of material of such equality of merit has proceeded from any eminent writer of our day. However profuse and discursive, De Quincey is always polished, and generally exact—a scholar, a wit, a man of the world, and a philosopher, as well as a genius. He looked upon letters as a noble and responsible calling; in his essay on Oliver Goldsmith he claims for literature the rank not only of a fine art, but of the highest and most potent of fine arts; and as such he himself regarded and practised it. He drew a broad distinction between "the literature of knowledge and the literature of power," asserting that the function of the first is to teach, the function of the second to move,—maintaining that the meanest of authors who moves has pre-eminence over all who merely teach, that the literature of knowledge must perish by supersession, while the literature of power is "triumphant for ever as long as the language exists in which it speaks." It is to this class of motive literature that De Quincey's own works essentially belong; it is by virtue of that vital element of power that they have emerged from the rapid oblivion of periodicalism, and live in the minds of a second generation

of readers and admirers, as they are safe to do in those of a third and fourth. The risk of their not reaching on through succeeding time arises from their diffuseness—their power is weakened by their volume.

De Quincey has fully defined his own position and claim to distinction in the preface to his collected works. These he divides into three classes:—"first, that class which proposes primarily to amuse the reader," such as the *Narratives, Autobiographic Sketches, &c.*; "second, papers which address themselves purely to the understanding as an insulated faculty, or do so primarily," such as the essays on Essenism, the Cæsars, Cicero, &c.; and finally, as a third class, "and, in virtue of their aim, as a far higher class of compositions," he ranks those "modes of unpassioned prose ranging under no precedents that I am aware of in any literature," such as the *Confessions and Suspiria de Profundis*. The high claim here asserted has been so far questioned; and short and isolated examples of eloquent apostrophe, and highly-wrought imaginative description, have been cited from Rousseau and other masters of style; but De Quincey's power of sustaining a fascinating and elevated strain of "impassioned prose" is allowed to be entirely his own. In this his genius most emphatically asserts itself, if it be not admitted that in that dread circle none durst walk but he, it will be without hesitation conceded that there he moves supreme. Nor, in regard to his writings as a whole, will a minor general claim which he makes be disallowed, namely, that he "does not write without a thoughtful consideration of his subject," and also with novelty and freshness of view. "Generally," he says, "I claim (not arrogantly, but with firmness) the merit of rectification applied to absolute errors, or to injurious limitations of the truth." Another obvious quality of all his genius is its overflowing fulness of allusion and illustration, recalling his own description of a great philosopher or scholar—"Not one who depends simply on an infinite memory, but also on an infinite and electrical power of combination, bringing together from the four winds, like the angel of the resurrection, what else were dust from dead men's bones into the unity of breathing life." It is useless to complain of his having lavished and diffused his talents and acquirements over so vast a variety of often comparatively trivial and passing topics, instead of concentrating them on one or two great subjects. The world must accept gifts from men of genius as they offer them, circumstance and the hour often rule their form. Those influences, no less than the idiosyncrasy of the man, determined De Quincey to the illumination of such matter for speculation as seemed to lie before him; he was not careful to search out recondite or occult themes, though these he did not neglect,—a student, a scholar, and a recluse, he was yet at the same time a man of the world, keenly interested in the movements of men and in the page of history that unrolled itself before him day by day. To the discussion of things new, as readily as of things old, aided by a capacious, retentive, and ready memory, which dispensed with reference to printed pages, he brought also the exquisite keenness and subtlety of his highly analytic and imaginative intellect, the illustrative stores of his vast and varied erudition, and that large infusion of common sense which preserved him from becoming at any time a mere *doctrinaire*, or visionary. If he did not throw himself into any of the great popular controversies or agitations of the day, it was not from any want of sympathy with the struggles of humanity or the progress of the race, but rather because his vocation was to apply to such incidents of his own time, as to like incidents of all history, great philosophical principles and tests of truth and power. In politics, in the party sense of that term, he would probably have been classed as a Liberal Conservative

or Conservative Liberal—at one period of his life perhaps the former, and at a later the latter. Originally, as we have seen, his surroundings were somewhat aristocratic, in his middle life his associates, notably Wordsworth, Southey, and Wilson, were all Tories, but he seems never to have held the extreme and narrow views of that circle. Though a flavour of high breeding runs through his writings, he has no vulgar successors at the vulgar. As he advanced in years his views became more and more decidedly liberal, but he was always as far removed from Radicalism as from Toryism, and may be described as a philosophical politician, capable of classification under no definite party name or colour. Of political economy he had been an early and earnest student, and projected, if he did not so far proceed with, an elaborate and systematic treatise on the science, of which all that appears, however, are his fragmentary *Dialogues* on the system of Ricardo, which John Ramsay M'Culloch pronounces "unequalled for brevity, pungency, and force." But political and economic problems largely exercised his thoughts, and his historical sketches show that he is constantly alive to their interpenetrating influence. The same may be said of his biographies, notably of his remarkable sketch of Dr Parr. Neither politics nor economics, however, exercised an absorbing influence on his mind,—they were simply provinces in the vast domain of universal speculation through which he ranged "with unconfined wings." How wide and varied was the region he traversed a glance at the titles of the papers which make up his collected—or more properly selected—works (for there was much matter of evanescent interest not reprinted) sufficiently shows. He was equally at home in all provinces, though never exerting his great powers so as to make himself paramount in any. Surprising as his literary achievements are, his capabilities were still greater; and the general survey leaves the impression of regret that, doing so much so well, he did not do more, or did not less better. Some things in his own line he has done perfectly; he has written many pages of magnificently mixed argument, irony, humour, and eloquence, which, for sustained brilliancy, richness, subtle force, and purity of style and effect have simply no parallels, and he is without peer the prince of dreamers. The use of opium no doubt stimulated this remarkable faculty of reproducing in skilfully selected phrase the grotesque and shifting forms of that "cloudland, gorgeous land," which opens to the sleep-closed eye; but the faculty itself was a speciality of his constitution, coloured by the quality of his genius, and enriched by the acquisitions of his intellect.

To the appreciation of De Quincey the reader must bring an imaginative faculty somewhat akin to his own—a certain general culture, and large knowledge of books, and men, and things. Otherwise much of that slight and delicate allusion that gives point and colour and charm to his writings will be missed; and on this account the full enjoyment and comprehension of De Quincey must always remain a luxury of the literary and intellectual. But his skill in narration, his rare pathos, his wide sympathies, the pomp of his dream-descriptions, the exquisite playfulness of his lighter dissertations, and his abounding though delicate and subtle humour, commend him to a larger class. Though far from being a professed humourist—a character he would have shrunk from—there is no more expert worker in a sort of half-veiled and elaborate humour and irony than De Quincey; but he employs those resources for the most part secondarily. Only in one instance has he given himself up to them unreservedly and of set purpose, namely, in the famous *Essay on Murder considered as one of the Fine Arts*,—an effort which, admired and admirable though it be, is also, it must be allowed, somewhat strained. He was a born critic and dreamer, a

logician by instinct and culture, a student by choice, a scholar by right of conquest of the stores of many minds, a writer of English of the first quality by dint of native command of language and life-long study and practice. His style, full and flexible, pure and polished, is peculiarly his own, yet it is not the style of a mannerist,—its charm is, so to speak, latent, the form never obtrudes; the secret is only discoverable by analysis and study. It consists simply in the reader's assurance of the writer's complete mastery over all the infinite applicability and resources of the English language. Hence involutions and parentheses, "cycle on epicycle," evolve themselves into a stately clearness and harmony, and sentences and paragraphs, loaded with suggestion, roll on smoothly and musically, without either fatiguing or cloying—rather, indeed, to the surprise as well as delight of the reader, for De Quincey is always ready to indulge in feats of style, watching the world with that sort of noble horsemanship which is as graceful as it is daring.

It has been complained that, in spite of the apparently full confidence of the *Confessions* and *Autobiographical Sketches*, readers are left in comparative ignorance, biographically speaking, of the man De Quincey. Two passages in his *Confessions* afford sufficient clues to this mystery. In one he describes himself "as framed for love and all gentle affections," and in another confesses to the "besetting infirmity" of being "too much of an eudæmonist." "I hanker," he says, "too much after a state of happiness, both for myself and others; I cannot face misery, whether my own or not, with an eye of sufficient firmness, and am little capable of surmounting present pain for the sake of any recessionary benefit." His sensitive disposition dictated the ignoring in his writings of traits merely personal to himself, as well as his ever-recurrent resort to opium as a doorway of escape from present ill, and prompted those habits of seclusion, and that apparently capricious abstraction of himself from the society not only of his friends, but of his own family, in which he from time to time persisted. He confessed to occasional accessions of an almost irresistible impulse to flee to the labyrinthine shelter of some great city like London or Paris,—there to dwell solitary amid a multitude, buried by day in the cloister-like recesses of mighty libraries, and stealing away by night to some obscure lodging. Long indulgence in seclusion, and in habits of study the most lawless possible in respect of regular hours or any considerations of health or comfort,—the habit of working as pleased himself without regard to the divisions of night or day, of times of sleeping or waking, even of the slow procession of the seasons, had latterly so disinclined him to the restraints, however slight, of ordinary social intercourse, that he very seldom submitted to them. On such rare occasions, however, as he did appear, perhaps at some simple meal with a favoured friend, or in later years in his own small but refined domestic circle, he was the most charming of guests, hosts, or companions. A short and fragile, but well-proportioned frame; a shapely and compact head, a face beaming with intellectual light, with rare, almost feminine beauty of feature and complexion; a fascinating courtesy of manner; and a fulness, swiftness, and elegance of silvery speech,—such was the irresistible "mortal mixture of earth's mould" that men named De Quincey. He possessed in a high degree what the American poet Lowell calls "the grace of perfect breeding, everywhere persuasive, and nowhere emphatic;" and his whole aspect and manner exercised an undefinable attraction over every one, gentle or simple, who came within its influence, for shy as he was, he was never rudely shy, making good his boast that he had always made it his "pride to converse familiarly more copaciously with all human beings—man,

woman, and child"—looking on himself as a catholic creature standing in an equal relation to high and low, to educated and uneducated. He would converse with a peasant lad or a servant girl in phrase as choice, and sentences as sweetly turned, as if his interlocutor were his equal both in position and intelligence; yet without a suspicion of pedantry, and with such complete adaptation of style and topic that his talk charmed the humblest as it did the highest that listened to it. His conversation was not a monologue, if he had the larger share, it was simply because his hearers were only too glad that it should be so; he would listen with something like deference to very ordinary talk, as if the mere fact of the speaker being one of the same company entitled him to all consideration and respect. The natural bent of his mind and disposition, and his life-long devotion to letters, to say nothing of his opium eating, rendered him, it must be allowed, regardless of ordinary obligations in life—domestic and pecuniary—to a degree that would have been not only culpable, but very highly so, in any less singularly constituted mind. It was impossible to deal with or judge De Quincey by ordinary standards—not even his publishers did so. Much no doubt was forgiven him, but all that needed forgiveness—and, after all, his sins were rather of omission than commission, trivial rather than heinous, trying rather than deadly—will soon be covered by the kindly oblivious veil of lapsing time, while his merits as a master in English literature will remain to be gratefully acknowledged.

A collection of De Quincey's works was published by James Hogg and Sons, Edinburgh, in 14 volumes, 1856-1860; and the same edition was republished by A. & C. Black, Edinburgh, with alterations and additions, in 16 volumes, 1862-1871. An American edition, issued by Ticknor & Fields, Boston, 1859-1868, extends to 20 disconnected volumes. A biography in two volumes, by H. A. Page, *Thomas De Quincey, his Life and Writings*, has been published by John Hogg and Co., London, 1877. (J. R. F.)

DERÁ GHÁZI KHÁN, a district of British India, in the Derajat division of the lieutenant-governorship of the Punjab, is situated between 28° 27' 0" and 31° 1' 0" N. lat. and 69° 36' 30" and 70° 58' 20" E. long. It is bounded on the N. by Derá Ismáíl Khán, on the E. by the Indus, on the S. by Jacobábád in Sind, and on the W. by the Sulámán range of hills. The district is a long narrow strip of country, 198 miles in length,¹ sloping gradually from the hills which form its western boundary to the River Indus on the east. Below the hills the country is high and arid, generally level, but sometimes rolling in snaky undulations, and much intersected by hill torrents, 201 in number. With the exception of two, these streams dry up after the rains, and their influence is only felt for a few miles below the hills. The eastern portion of the district is at a level sufficiently low to benefit by the floods of the Indus. A barren tract intervenes between these zones, and is beyond the reach of the hill streams on the one hand and of the Indus on the other. Although liable to great extremes of temperature, and to a very scanty rainfall, the district is not unhealthy. The rainfall in 1872-73 was 7.7 inches; the mean temperature 79° Fahr. The maximum temperature (112°) occurred in June, the minimum (40°) in December. The principal agricultural products are wheat, great millet, *joár*, cotton, rice, and indigo. The poppy plant is also rather extensively cultivated in the south of the district. The less important food grains are barley, spiked millet (*bágrá*), and pulses. Oil seeds and tobacco are also grown to a small extent.

¹ The area of the district is returned at 4950 square miles, or 3,168,000 acres, of which 2,412,749 acres were under assessment in 1872-73. The cultivated area amounts to 1662 square miles, or 1,063,680 acres, or 33.57 per cent of the total area. Of the cultivated area 427,599 acres, or 40.24 per cent, are irrigated. The first regular land settlement of the district was concluded in 1872.

cultivation mainly depends upon artificial irrigation, effected principally by canals leading from the Indus. In 1872-73 there were 15 main canals, drawing their supply direct from the Indus, of which 2 were the property of private individuals, and 13 were under the management of Government. Alum, earth salt, and *raggi* (an impure carbonate of soda) are manufactured in some quantities. The exports are indigo, opium, salt, dates, wheat, cotton, barley, millet, *zhi*, and hides. The imports are sugar, fruits from Cabul, gram, woollen goods, English piece goods and broad cloth, metals, salt, and spices. The total revenue of the district in 1872-73, exclusive of local funds and canal collections, amounted to £45,161, of which £35,588, or 79 per cent., was derived from the land. The administrative staff of the district consists of a deputy commissioner, with two assistants and one extra assistant, four tahsildars, each with a deputy or assistant, a district superintendent of police, and two civil surgeons. The police force numbered 733 men. There are 35 schools, maintained or assisted by the state, and 132 indigenous village schools—total 167, attended in 1872-73 by 2907 pupils. Three charitable dispensaries afford gratuitous medical relief. The principal town of the district, and chief seat of commerce, is Derá Gházi Khán, situated on the west bank of the Indus, 30° 4' lat., 70° 51' long. Population in 1868.—Mahometans, 10,699; Hindus, 8850; Sikhs, 328; Christians, 52, "others," 194—total, 20,123. The other towns containing a population exceeding 5000 souls are Jampur, population 7796; Choti, population 7300; Dágil, population 5693; and Rájhan, population 5656. Rájhanpur, although not containing 5000 inhabitants, is important as a cantonment, a regiment of cavalry and two companies of infantry being stationed there. The foregoing towns are all municipalities.

The census of 1868 returned the population as follows:—Mahometans, 264,527, Hindus, 38,467; Sikhs, 1124; "others," 4722, total 308,840. The Beluchis, who are Mahometans, form by far the most important section of the population, and number 82,590. The Játs, who are also Mahometans, are the most numerous, numbering 162,519. Among the Hindu population, the Aroras form the most important caste, 33,024 in number, principally traders. Of the total population, 164,729, or 53 per cent., are returned as agriculturists.

DERÁ ISMÁIL KHÁN, a district of British India in the Deráját division of the lieutenant-governorship of the Punjab, is situated between 30° 35' 30" and 32° 33' 0" N. lat., and 70° 15' 0" and 72° 3' 20" E. long. It is bounded on the N. by the district of Bannu, on the E. by Sháhpur and Jhang, on the S. by Muzaffargarh and Derá Gházi Khán, and on the W. by the Suláimán hills, which mark the frontier. The district is divided into two almost equal portions by the Indus, which intersects it from north to south, and is the only river of any importance. To the west of the Indus, the characteristics of the country resemble those of Derá Gházi Khán. To the east of the present bed of the river there is a wide tract known as the *Kachhi*, exposed to river action. Beyond this, the country rises abruptly, and a barren, almost desert plain stretches eastwards, sparsely cultivated, and inhabited only by nomadic tribes of herdsmen. The area of the district is 7096.56 square miles, or 4,541,800 acres; the cultivated area amounts to 541,913 acres, of which 428,604 acres are under irrigation, and 113,309 unirrigated. The uncultivated area, which is returned at 3,999,887 acres, is subdivided as follows:—grazing lands, 364,864 acres, cultivable, but not actually under cultivation, 1,329,796 acres; uncultivable, 3,999,887 acres. The district has recently been granted a regular land settlement for the first time. The period of the latest summary settlement expired in 1868 in part of the district, and in 1871 in the remainder. The principal agricultural products are wheat, barley, gram,

pease, tobacco, and oil-seeds for the spring or *rabi* harvest; and rice, millets, and cotton for the autumn or *kharif* crop. There are no manufactures of importance. The principal municipalities and trading towns, with their populations (1863), are as follows.—Derá Ismáil Khán, the civil station and chief town, population 24,906, Leid, 17,033; Koláchi, 9921; Takhwára, 6800; Karor, 5720, Buakkar, 5554, Panmala, 5502. Other minor towns, which are also municipalities, are Kot Sultán, Mankherá, and Tánk. The income of the district in 1872-73 (exclusive of municipal taxation) amounted to £50,918, of which £39,784 was derived from the land. The police force consisted of 617 men. There were 18 Government or aided and 87 indigenous village schools in 1872-73, attended by 2190 pupils.

The census of 1868 returned the population as follows:—Mahometans, 338,387; Hindus, 48,756; Sikhs, 1587, others 6134; total 394,864. Of the Mahometan population, the principal classes are the Beluchis, 34,703 in number, Pathans, 51,823, and Sayyids, 8669. The Hindus consist almost entirely of Aroras, 42,087, principally traders and money lenders. Of the total population, 187,096, or 48 per cent., are returned as agriculturists.

DERAJÁT, a division or commissionership of British India, under the jurisdiction of the lieutenant-governor of the Punjab, comprising the frontier districts of Derá Gházi Khán, Derá Ismáil Khán, and Bannu, situated between 28° 27' 0" and 33° 15' 30" N. lat. and 70° 15' 0" and 72° 3' 20" E. long. The division is bounded on the N. by the district of Kohát, on the E. by the districts of Rawal Pindi, Sháhpur, and Jhang, and by the River Indus, on the S. by the district of Jacobábád in Sind, and on the W. by the Wazirí and Suláimán hills, beyond British territory. The two northern districts of the division, Bannu and Derá Ismáil Khán, are intersected by the Indus. The Bannu valley is drained by the Kuram and Gambila rivers. It is shut in on the N. and S. by hills, and is traversed from N. to S. by a continuation of the great Punjab salt range. According to the census of 1868, the Deráját division comprises an area of 14,432 square miles, with a population of 991,251 souls, inhabiting 1695 villages, classified as follows:—Mahometans, 863,464, or 87.1 per cent., Hindus, 113,445, or 11.5 per cent., Christians, 341; Sikhs, 3204, or .3 per cent., and "others," 10,797, or 1.1 per cent.

DERBEND, or DERBENT, a town of Russia, in the government of Daghestan, on the western shore of the Caspian, about 170 miles E.N.E. of Tiflis, in 42° 4' N. lat. and 47° 53' E. long. It occupies a narrow strip of land lying between the sea and a mountain ridge of moderate elevation, which is crowned by the citadel, or Narín Kalé; and on all sides except towards the east, where it projects into the water, it is surrounded by strong walls built of porous limestone. Its general aspect is decidedly Oriental, owing to the flat roofs of its two storied houses. Besides the governor's residence, which stands in the neighbourhood of the citadel, the town possesses a fine Russian church, 3 Jewish synagogues, 17 mosques (including one belonging to the Sunna sect), 3 bazaars, and a number of caravanserais. The upper part of the town is supplied with water from a reservoir in the citadel, fed by a fountain in the mountain behind; but the Dubar, or lower town along the shore, communicates by an aqueduct with the Rubas-Chai, a small river to the south. The environs are occupied by vineyards, gardens, and orchards, in which madder, saffron, and tobacco, as well as figs, peaches, pears, and other fruits are cultivated. The madder is a valuable export, and the saffron is in high repute. Earthenware, weapons, and silk and cotton fabrics, are the principal products of the manufacturing industry. To the north of the town is the monument of the *Kul Lar*, or Forty Heroes of Daghestan, whose valour is commemorated in Arabic inscriptions; and to the south lies the seaward extremity of the great Derbend or Caucasian wall, otherwise known as

Sold-Eskender, or Alexander's wall, which, while still entire, had a height of 29 feet and a thickness of about 10, and with its iron gates and numerous watch towers formed a valuable defence of the Persian frontier. Derbend is a place of great antiquity, and is usually identified with Albana, the capital of the ancient Albania. The modern name, which is the Persian word for a gateway, probably came into use about the end of the 5th or the beginning of the 6th century, when the city was re-founded by Kobod of the Sassanid dynasty. The walls and the citadel are believed to belong to the time of Kobod's son, Nushirvan Chosroes. In 725 the Arabs entered into possession, and established a Khanate in the city, which they called either Bab-el-abrab, "the principal gate," Bab-el-Khadid, "the iron gate," or Saril-el-Dagab, "the golden throne." The celebrated caliph, Haroun-al-Rashid, lived in Derbend at different times, and brought it into great repute as a seat of arts and commerce. In 1220 it was captured by the Mongolians, and in the course of the succeeding centuries it frequently changed masters. In the reign of Feodor Ivanovich, the Persian Government promised to make it over to Russia in reward for assistance against the Turks, but the surrender was never completed. In 1722 Peter the Great took advantage of the disturbances in Persia, seized the town, established a garrison, and intrusted the government to Imam Kuli-Beg; but in 1733 the supremacy of the Persian Nadir Shah was again recognized. Captured in 1760 by Fut Ali Khan, and governed after his death by his brother Sheikh Ali, the town was in 1796 besieged by the Russians both by land and sea, and in 1813 formally incorporated by the treaty of Gulistan with the Russian empire. In 1831 it was vainly attacked by Kazi-mull. Population in 1873, 15,739.

PLATE II. DERBY, COUNTY OF, lies as nearly as possible in the centre of England, being about equally distant from the eastern and western seas. In the time of the Britons it was part of the district which constituted the kingdom of the Cornovii. While under the Roman sway it formed a part of *Britannia Prima*, and under the Heptarchy it belonged to the kingdom of Mercia. It is bounded on the E. by Nottinghamshire and a part of Leicestershire, on the W. by Staffordshire and Cheshire (from which it is separated by the rivers Trent, Dove, Etherow, and Goyt), on the N. by Yorkshire and a part of Cheshire, and on the S. by Leicestershire. Its greatest length from S.E. to N.W. is 56 miles, its greatest width from N.E. to S.W. is 33 miles. It contains an area of 656,243 statute acres, equal to about 1025½ square miles. Its population in 1851 amounted to 296,044 persons, in 1861 to 339,327, and in 1871 to 379,394 of whom 190,657 were males, and 188,737 females. From the beginning of the century down to 1871, 15 per cent. was the mean rate of increase in each intermediate period of ten years; while from 1861 to 1871 the total increase was 40,967, or at the rate of nearly 12 per cent. For practical purposes the population may be taken at 400,000, giving an average of 6.60 persons per acre, or 1.64 acres per person. The rental of the county, as given in the Owners of Land Return, 1873, was £1,657,995.

Derbyshire is divided into the hundreds of High Peak, Scarsdale, Appleton, Repton and Gresley, Morleston and Litchurch, and the wapentake of Wirksworth. It consists of 331 parishes, townships, and parts of parishes. It has a court of quarter sessions, and is included as an archdeaconry in the diocese of Lichfield. For electoral purposes the county has been formed into the 3 divisions of east, north, and south, each returning 2 members to Parliament, and thus, with the 2 members from the borough of Derby, is represented by a total of 8 members.

The geographical or physical aspect of Derbyshire is

very diversified. The southern part presents little that is picturesque, or in any way striking, being for the most part a level surface, with occasional slight undulations. In its northern portions, however, particularly in the bold and mountainous regions of the High Peak, there are imposing combinations of those features which go to constitute impressive and romantic scenery. In the more hilly districts, some of the valleys and dales are very beautiful, notably the valleys of Castleton and Glossop, Dovedale, Millersdale, and the dale of Matlock. Derbyshire is on the whole a well-wooded county, and in the spacious parks surrounding the numerous mansions of noblemen and others which it contains, may be seen many fine oaks of noble appearance, those at Kedleston, the seat of Lord Scarsdale, three miles from Derby, being considered among the largest and oldest in the kingdom.

The climate, as might be expected from the diversified configuration of the land, varies very considerably in different parts. From the elevation which it attains in its northern division the county is colder and is more frequently visited with rain than other midland counties. In summer cold and thick fogs are often seen hanging over the rivers, and clinging to the lower parts of the hills, and hard frosts are by no means unknown even in June and July. Owing to the great elevation some kinds of grain will not grow at all in many of the northern parts, while that which is sown in the more sheltered spots is exceptionally late in coming to maturity. The winters there are generally severe, and the rainfall heavy. At Reiper, in 1876, there were 36.01 inches of rain during the year, while the average for the five years was 32.69 inches per annum.

The elevation of the land proceeds gradually from south to north, the greatest altitudes being attained in the north division of the county, which is of a distinctly mountainous character. The mountains (or the plateau) of North Derbyshire may be said to form the central watershed of England, containing the source of many large rivers—as the Don, the Trent, and the Mersey. The highest altitudes are Kinder Scout (1981 feet), the Peak (1856), and, on the borders of Cheshire and Staffordshire, Axe Edge (1751).

From Axe Edge the streams of the county radiate. Those of the north-west belong to the Mersey, and those of the north-east to the Don, but all the others to the Trent, which, like the Don, falls into the Humber. The principal river is the Trent, which, rising in the Staffordshire moorlands, does not intersect this county, but forms its south-west boundary for some distance, separating Derbyshire from Staffordshire on the south. After the Trent the most important river is the Derwent, one of its tributaries, which, taking its rise in the lofty ridges of High Peak, flows southward through a succession of striking and beautiful scenery, receiving a number of minor streams in its course. The other principal rivers are the following. The Dane rises at the junction of the three counties, Yorkshire, Cheshire, and Derbyshire. The Goyt has its source a very little further north, at the base of the same hill, and, taking a N.N.E. direction, divides Derbyshire and Cheshire, and falls into the Mersey. The Dove rises on the southern slope, and flows on as the boundary stream between Derbyshire and Staffordshire for about 45 miles. It receives several feeders, and falls into the Trent at Repton. The Erewash is the boundary between Notts and Derbyshire. The Rother rises about Baslow, and flows north-east into Yorkshire. A little more to the west are the Sheaf, Wallin, Poulter, and Ryton, which flow into the Don at Sheffield.

Canals.—There are numerous canals intersecting this county in various directions. The Trent and Mersey or Grand Trunk canal, communicating between Liverpool and

London, and also with Bristol and Hull, was begun in 1776 by the celebrated Brindley, a native of the county, and completed under Smeaton and Rennie. It passes through Derbyshire from Burton, following the course of the Trent. The Chesterfield canal was begun in 1771 by Brindley, and completed by his brother-in-law, Mr Henshall, in 1776. It enters the county at Killamarsh, and terminates at Chesterfield. There are also the Langley Bridge or Erewash canal, the Peak Forest canal, the Ashton-under-line, the Cromford, the Ashby-de-la-Zouch, the Derby, and the Nutbrook canals.

Nowhere have railways received a more complete development than in this county, and nowhere are their beneficial effects more apparent. For this the system of the Midland Company must claim the chief credit. The roads in Derbyshire are numerous, and generally in good condition. The great road from London to Manchester crosses the Trent near Shardlow, and passes through Derby and Ashbourne into Staffordshire.

Geology, Minerals, &c—With the exception of drift gravel, and some alluvial deposits, the rocks of this county belong to the Palæozoic and Mesozoic periods. The mountain limestone underlies all the other rocks, and in the Peak district rises to a great elevation. It is in this formation that the well-known caves of Derbyshire occur. The calcareous rocks are confined to the western side of the county,—Tissington being the southern, Castleton the northern, Axe Edge the western, and Matlock the eastern extremities. There is also an outcrop at Crich. The intrusive beds of toadstone (some of which attain a thickness of 200 feet) and volcanic mud mark great submarine eruptions when this ancient lava was spread over the sea-bottom. It is estimated that upwards of half a million tons are worked yearly. The marbles are numerous and valuable for ornamental purposes. Derbyshire also contains several metallic ores—viz, galena, barytes, zinc, calamine, fluor spar, and elaterite. Galena (sulphide of lead) is obtained rather extensively, some mines near Castleton having been worked by the Romans. In 1874 the quantity raised was 4301 tons, from which were extracted 800 ounces of silver. In connection with galena zinc is found, of which 4050 tons were raised in 1876; of calamine (carbonate of zinc) 30 tons. Barytes is used as an inferior white paint, and also for ornamental purposes. The total output for 1876 was 2700 tons. Blue john is a somewhat rare fluor spar, impregnated with oxide of manganese. It is one of the most ornamental minerals of the county, and is much used in the manufacture of tazzas, brooches, &c. In one or two places a thin seam of coal is found in the mountain limestone. Copper was once worked in this formation at Eoton, on the border of the county, but it has never been abundant. Traces of gold have also been found in toadstone. Chert is got near Bakewell, and is used for the manufacture of porcelain. The most remarkable and rare mineral is elaterite, or elastic bitumen, found at Windy Knoll, near Castleton. It is found only at two other places—at Montrelaix in France, and in Connecticut, United States. The fauna of this formation may be briefly tabulated as follows, from Etheridge's list—Coelenterata, 54 species; Echinodermata, 27; Crustacea, 15; Brachiopoda, 96; Lamellibranchiata-Monomyriata, 29; Gasteropoda, 55; Cephalopoda, 31; Pisces, 12. The surface soils of the mountain limestone are very unproductive, and, as a rule, can only be used for grazing. The Yoredale rocks make a narrow margin round the above formation, forming also the range of hills between Hope and Edale valleys, and extends to the north of the Peak, attaining a thickness of 500 feet. As is usual with this rock, frequent landslips take place, notably at Alport Tower, Dove Holes, and at the southern flank of Mam-Tor, the

latter having carried with it part of the old Roman camp, &c. The Millstone Grit is part of a large formation stretching into adjacent counties. It is a long, narrow outcrop, running from north to south on the whole western side of the Coal Measures from Stanedge Pole to Little Eaton. There is also an outcrop, 200 feet thick, south of the Trent. The high table-land of the Peak is of this formation. It is a valuable building-stone, and as such it is extensively used, as well as for millstones, from which it derives its name. The Coal Measures are the southern continuation of the great Yorkshire coal-field. They occupy the larger portion of the eastern side of the county from a few miles south of Sheffield to near Balborough Hall, where they disappear under the Permian. The coal-field (which extends into Notts) covers an area of about 700 square miles, 230 of which are in this county. At Shireoaks the top hard coal is worked, at a depth of 510 yards, the overlying Permian rock being only 200 feet thick. The principal coals worked are the deep soft and deep hard, both important. Still more so is the clod, or black shale; but the best of all is the Kilbourne, near Belper, which is equal to the best Newcastle. Upwards of 10,000 people are employed in the Derbyshire coal-fields, which produce annually more than 7,000,000 tons. The ironstones associated with this coal-field are very valuable, yielding upwards of 130,000 tons annually. The Permian is represented in the north-east by a narrow strip of Magnesian Limestone, which is said to be one of the best building stones in the kingdom. The surface soils of this formation are probably the most fertile in the county, its barley or malt having become famous. A narrow strip of the Bunter stretches just on the edge of the Yoredale, from Ashbourne to Quarndon, and patches occur to the north of Breadsall, at Sandiacre, and in the neighbourhood of Repton. The Keuper Red Marl and Sandstone occupy the larger part of South Derbyshire, the most northerly point being near Ashbourne. The sandstones are extensively used for building purposes. An important bed of gypsum is worked at Chellaston, which is burnt and pulverized for making plaster of Paris,—the white variety being made into chimney ornaments, statuettes, &c. The Drift Gravel is confined almost to the south and east of the county. Near Derby it is very abundant. Much light has been thrown upon the fauna of the Pleistocene period by the researches of Mr Pennington at Castleton, and Messrs Mills and Heath at Cresswell. The more rare and important "finds" are the mammoth, woolly rhinoceros, Irish elk, reindeer, cave bear, wolf, British lion, hyæna, glutton, Arctic fox, machiærodus (†), &c., and a large collection of palæolithic implements. Peat bogs are spread over all the moorland districts of the Yoredale and Millstone Grit.

Agriculture—In the valley of the Trent a large surface is laid down in permanent grass, being devoted to cattle-feeding and dairy purposes, while heavy crops of wheat, turnips, &c., are grown in other parts of the district. Dairy farms are numerous; and Derbyshire cheese, which holds a high reputation, is annually sent to the metropolis, or to the seaports for exportation. Cheese fairs or markets are held in various parts of the county, as at Derby, Burton-on-Trent, Ashbourne, Uttoxeter, and Loughborough. Barley is much cultivated, especially about Repton and Gresley, and also in the east of the county, the inducement being great from the proximity of Burton, the great seat of the brewing industry. In the upland districts, where the soil is poor and the climate harsh and unfriendly, agricultural industry is much less important and profitable. It is chiefly devoted to the feeding of sheep. The following figures, taken from the Agricultural Returns for 1873 and 1876, shows the distribution of the agricultural acreage of the county, and the numbers of live stock, in those years:—

	Under all kinds of Crops	Corn Crops	Green Crops	Grass under rotation
1873	438,674	74,240	20,806	35,967
1876	502,791	68,933	21,837	36,259

In 1876 wheat and oats constituted each one-third of the corn crops, and barley a fourth; turnips formed one-half of the green crops.

	Horses.	Cattle	Sheep	Pigs.
1873 ..	18,004	136,339	263,429	40,078
1876 .	20,618	134,891	242,732	38,361

A marked feature of the upland districts is the total absence of hedges, and the substitution of limestone walls, put together without any mortar or cement. The county possesses a flourishing agricultural society, which holds a show of cattle and other live stock annually.

In respect of the ownership of the land, Derbyshire in 1873 was divided among 19,866 separate proprietors, whose gross estimated rental amounted to £1,764,689. The average size of each property in that year was 31 acres, while that of all England was 34 acres; and the average value per acre was £2, 16s 10d, that of all England being £3, 0s. 2d. There were 12,874 owners holding less than one acre of land, equal to 65 per cent. of the total number of proprietors, or about 6 per cent. fewer than the average of small owners in all England. Eight proprietors held more than 6000 acres each, viz.—duke of Devonshire (Chatsworth), 83,829 acres; duke of Rutland (Haddon Hall), 26,973; Sir J. H. Crewe, Bart. (Calke Abbey), 12,923; Lord Scarsdale (Kedleston), 9166; Lord Howard (Glossop Hall), 9108; duke of Portland, 7740; T. W. Evans (Allestree), 6799; Lord Vernon (Sudbury Hall) 6154.

Manufactures—These are both numerous and important, embracing silks, cotton hosiery, iron, woollen manufactures, lace, elastic web, and brewing, for which see BURTON. For many of these this county has long been famous, especially silk, which is carried on to a large extent in Derby, as well as in Belper and Duffield, where the first silk mill in England was set up by a mechanic, John Lombe, who introduced it from Italy. Cotton was also at one time an important industry, but has in great measure passed into the county of Lancashire. It was introduced here by the celebrated Sir Richard Arkwright in 1771. Hosiery also was much in vogue, and obtained great celebrity from the invention of Mr Strutt, by which “ribbed” stockings could be made—the Derby “rib” having been long the familiar designation of the article produced by Strutt’s invention. There are numerous iron foundries, machine and iron-bridge works, &c., in Derbyshire, those in the county town alone employing a great many hands. Silk-throwing is a principal industry of Derby, which in ordinary times gives employment to 3000 or 4000 persons, chiefly females. Elastic web weaving by power looms is carried on to a great extent, and the manufacture of lace and net curtains, gimp trimmings, braids, and cords. In the county town and neighbourhood are several important chemical and colour-works; and in various parts of the county, as at Belper, Cromford, Matlock, Tuthury, &c., are extensive cotton-spinning mills, as well as hosiery and tape manufactories.

Ecclesiastical Buildings.—Derbyshire is distinguished for numerous old and interesting churches. The prevailing style of the churches is the Norman, and next to that the Early English, the style which immediately succeeded it. Steeple Chapelry, near Whitwell, on the east side of the county, is Norman; and of this church Mr C. Cox, in his work on Derbyshire churches, says that it is “the most complete and beautiful specimen of Norman work, on a small scale, that can be met with anywhere in this country or in Normandy.” It was probably built during the reign of Stephen, 1135–54.

The *antiquities* of Derbyshire are of considerable interest. One of the more noteworthy is a causeway, or Roman paved road, called Bathgate, running seven miles from Buxton to a small village called Brough, which road from its name seems to indicate that the Buxton waters were known to the ancients. Rocking-stones exist near Rowter and at other places; Druidical remains, in the form of a Druidical temple, on Stanton moor, with a large number of associated objects which seem to justify the assumption that it has been inhabited by Druids. On Hartlo moor, at Arbelow, is another Druidical temple, with its barrows and tumuli; there are others on the moor near Eyam, and near Edale. Barrows are found at Arbelow, Brassington, on the moor near Eyam, and at Tissington. At Taddington is one of the most perfect examples now existing. Roman stations are to be found near Buxton, at Little Chester (which is the old Roman town *Derventio*), and at Mam-Tor, near Castleton, where there is also an encampment. At Repton, in 660, “there was a noble monastery of religious, of both sexes, under an abbess, after the old Saxon fashion, wherein several of the royal line were buried.” This was afterwards destroyed by the Danes, when Maud, widow of Ranulph, second earl of Chester, built a priory for Black Canons in 1172. Here the Mercian kings who resided at Tamworth were buried. At Melbourne is a castle which was a royal demesne at the Conquest, and where John, duke of Bourbon, taken at the battle of Agincourt, was kept nine years in the custody of Nicholas Montgomery the younger.

DERBY, the county town of Derbyshire, is a corporate and borough town, sending two representatives to Parliament, and consisting of five parishes. It is situated chiefly on the western bank of the river Derwent, upon ground of varying heights, and is surrounded with gentle eminences, from which flow the Markeaton and other brooks. It occupies a position almost in the centre of England, 127 miles N.W. of London.

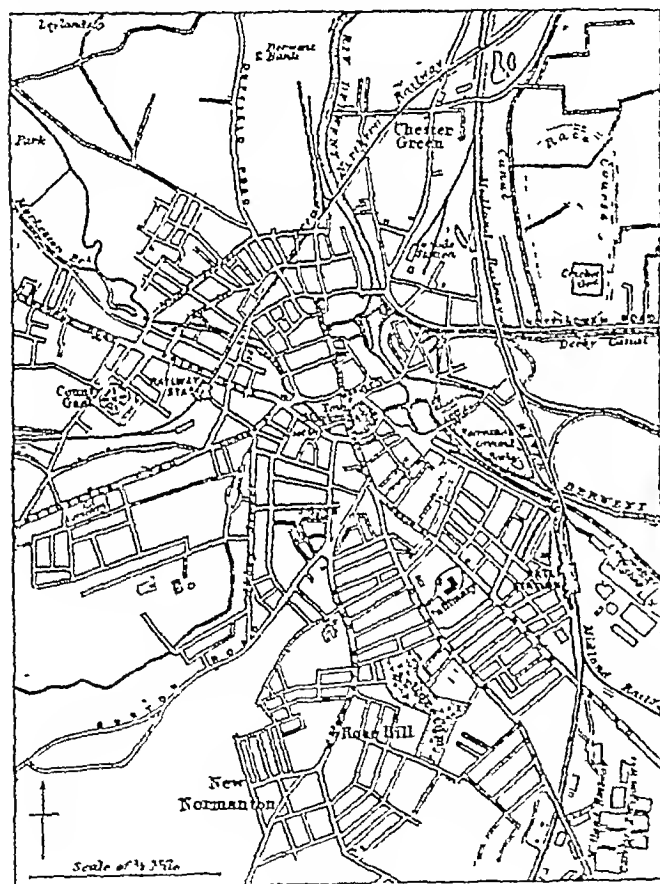

Derby possesses several large public buildings, including the town hall, a spacious range of buildings recently erected for the postal and telegraph departments and the inland revenue offices, the county gaol, a new masonic hall, All Saints Church, the tower of which (174 feet high) is considered one of the finest in the midland counties, and a Roman Catholic church (one of the best examples of Pugin). The Derby grammar school, an ancient foundation which occupies St Helen’s House (once the town residence of the Strutt family), has lately had class-rooms added to it, erected by public subscription as a memorial of the visit of the Prince and Princess of Wales. There are flourishing schools of art and science, a large and commodious infirmary for town and county, an arboretum of 17 acres, given to the town in 1840 by the late Joseph Strutt, Esq., a market square, a market hall, and water-works erected at a cost of £40,000, and since greatly extended. A recreation ground, free public swimming baths, a free library, and museum buildings have all been presented to the town by Mr M. T. Bass. Since about 1850 Derby has been greatly improved and extended, owing chiefly to the impulse given by the establishment of the head offices and principal workshops of the Midland Railway Company, and will be still further improved by the construction now in process of a branch of the Great Northern Railway, which passes through the town over a long series of arches.

Seal and Arms of Derby.

Derby has been long celebrated for its porcelain, which rivalled that of Saxony and France. This manufacture was introduced in the year 1750, and although for a time partially abandoned, it has been so far revived, and is still continued. There are also spar works where the fluor spar, or blue john, is wrought into a variety of useful and ornamental articles. The manufacture of silk, hosiery, lace, and cotton formerly employed a large portion of the population, and there are still numerous silk mills and elastic web works, &c. The iron manufacture is also of great importance; among the larger establishments may be mentioned the Britannia Works, which furnished the roof of the great Agricultural Hall, London.

The sanitary condition of the town is much improved since the formation of a local board, and the rate of mortality is low. Among benevolent institutions may be mentioned a ragged school, and a nurses' "home." The population of the municipal borough, which occupies an area of 1796 acres, numbered 40,609 persons in 1851, 43,091 in 1861, and 49,810 in 1871. The parliamentary borough, which in 1867 was extended so as to include the townships of Litchurch and Little Chester, and covers an area of 2999 acres, had a population in 1871 of 61,381—29,882 males and 31,499 females.

Plan of Derby

Derby is a town of great antiquity, but its origin is unknown. During the Heptarchy it was called Northworchig, and its present name Derby, or Deoraby, is due to the Danes. Constituted in the ninth century the chief town of the county by King Segurd, Derby was incorporated by Henry I. Its charter was surrendered to Charles II in 1680, and a new one was granted in 1683, by which the government of the borough was vested in a mayor, 9 aldermen, 14 brethren, and 14 capital burgesses. In 1835 the town council was re-organized under the Municipal Corporations Act, and now consists of a mayor, 12 aldermen, and 36 councillors. Derby was the furthest place reached by

the Pretender in his march towards London in 1745; he lodged in Exeter House, Full Street, and held there a council of war, which resulted in the abandonment of his project.

DERBY, EDWARD-GEOFFREY SMITH STANLEY, FOURTEENTH EARL OF, Baron Stanley of Bickerstaffe, and a baronet (1799–1869), born at Knowsley in Lancashire, on the 29th March 1799, was the eldest son of Lord Stanley, who afterwards (1834) became the thirteenth earl of Derby. The title in the direct line of succession to which he was thus born ranks second in precedence among the earldoms in the peerage of England. He was educated at Eton and at Christ Church, Oxford, where he distinguished himself as a classical scholar, though he took only an ordinary degree on quitting the university. In 1819 he obtained the Chancellor's prize for Latin verse, the subject being "Syraeuse." He gave early promise of his future eminence as an orator, and it is said that in his youth he used to practise elocution under the instruction of Lady Derby, his grandfather's second wife, who as Miss Eliza Farren had been a celebrated actress. With such an inclination and aptitude for public speaking, the heir to an ancient title was only fulfilling his natural destiny in seeking a seat in the House of Commons, and of course he had no difficulty in finding one. In 1820, soon after he had attained his majority, he was returned for Stockbridge in Hampshire, one of the nomination boroughs whose electoral rights were swept away by the Reform Bill of 1832, Stanley, like several others who entered parliament by means of them, being a warm advocate of their destruction. It may appear somewhat strange that he should have remained for four years, so far as is known, a silent member, but the representative of a pocket borough had no constituency to consider, and there was not in those days the incentive to frequent speaking that is now furnished by full daily reports of the debates circulating through the entire country. His maiden speech was delivered early in the session of 1824 in the debate on a private bill for lighting Manchester with gas. Although the subject can scarcely have given scope for any high flight of oratory, the speaker was warmly complimented by Sir James Mackintosh, one of the first authorities in the House, who welcomed him as an accession to the Liberal ranks, and Hausard reports the speech as characterized by "much clearness and ability." His second appearance was made in connection with a subject—irrepressible as it proved, though he always did his utmost to repress it—which was afterwards to determine more than one important turning point in his political career, and to call forth his last utterance in parliament. It is noteworthy also as an early exhibition of the Conservative instinct whose growing strength led gradually to an entire change of his political position. On the 6th May 1824, he delivered what seems to have been a vehement and eloquent speech against Joseph Hume's motion for a reduction of the Irish Church establishment, maintaining in its most conservative form the doctrine that church property is as sacred as private property. From this time his appearances became frequent; and he soon asserted his place as one of the most powerful

speakers in the House. Specially noticeable almost from the first was the skill he displayed in reply. Macaulay, in an essay published in 1831, remarked that he seemed to possess intuitively the faculty which in most men is developed only by long and laborious practice. "Indeed, with the exception of Mr Stanley, whose knowledge of the science of parliamentary defence resembles an instinct, it would be difficult to name any eminent debater who has not made himself a master of his art at the expense of his audience."

In the autumn of 1824 Stanley went on an extended tour through Canada and the United States in company with Mr Labouchere, afterwards Lord Taunton, and Mr Evelyn Denison, afterwards Lord Ossington. In May of the following year he married the second daughter of Edward Bootle-Wilbraham, created Baron Skelmersdale in 1828, by whom he had a family of two sons and one daughter who survived, besides three children who died in infancy.

At the general election of 1826 Stanley renounced his connection with Stockbridge, and became the representative of the borough of Preston, where the Derby influence has usually, though not invariably, been paramount. The change of seats had this advantage, that it left him free to speak against the system of rotten boroughs, which he did with great force during the Reform Bill debates, without laying himself open to the charge of personal inconsistency as the representative of a place where, according to Gay, cobblers used to "cast three years upon one vote." In 1827 he and several other distinguished Whigs made a coalition with Canning on the defection of the more unyielding Tories, and he commenced his official life as under-secretary for the colonies. Whether the coalition arrangement would have proved stable had its distinguished leader survived is more than questionable, but it was entirely broken up by his death in August of the same year. Lord Goderich, who had been Stanley's chief at the Colonial Office, succeeded to the premiership, but he never was really in power, and he resigned his place after the lapse of a few months without venturing to meet parliament. During the succeeding administration of the duke of Wellington (1828-30), Stanley and those with whom he acted were in opposition. His robust and assertive Liberalism about this period sounds somewhat curiously to a younger generation who knew him only as the very embodiment of Conservatism. They can find little of the earl of Derby except his characteristic force of expression in the conviction uttered by Stanley, "that the old and stubborn spirit of Toryism is at last yielding to the liberality of the age—that the Tories of the old school, the sticklers for inveterate abuses under the name of the wisdom of our ancestors, the *laudatores temporis acti* are giving way on all sides." Even the most retrograde political party, however, makes distinct progress almost in spite of itself as the years pass on, and Lord Derby might very well have maintained that the Toryism he represented in his maturity was not the Toryism he had denounced in his youth.

By the advent of Lord Grey to power in November 1830, Stanley obtained his first opportunity of showing his capacity for a responsible office. He was appointed to the chief secretaryship of Ireland, a position in which, as it turned out, he found ample scope for both administrative and debating skill. On accepting office he had, according to the usual practice, to vacate his seat for Preston and seek re-election; and it must have been peculiarly mortifying to one of his high spirit that, in spite of his family influence and growing reputation, he alone of all the members of the new ministry in the Lower House failed to secure his

return. He was defeated, and the defeat was doubtless rendered more bitter by the fact that his opponent was the Radical "orator" Hunt. The contest was a peculiarly keen one, and turned upon the question of the ballot, which Stanley refused to support. He re-entered the house as one of the members for Windsor, Sir Hussey Vivian having resigned in his favour. In 1832 he again changed his seat, being returned for North Lancashire, which he continued to represent until his elevation to the House of Lords.

Mr Stanley was one of the most ardent supporters of the great measure which has made Lord Grey's administration the most memorable of the present century. Of this no other proof is needed than his frequent parliamentary utterances, which were fully in sympathy with the popular cry "The bill, the whole bill, and nothing but the bill." Reference may be made especially to the speech he delivered on the 4th March 1831 on the adjourned debate on the second reading of the bill, which was marked by all the higher qualities of his oratory. More than thirty years later, when he was premier, he was again called upon to deal with the question, and he had statesmanship enough to settle it on a permanent basis, but the incertitude with which he then took what he himself in a well remembered phrase called "a leap in the dark" was in curious contrast to the clear conviction with which he advocated the earlier measure.

Apart from his connection with the general policy of the Government, Stanley had more than enough to have employed all his energies in the management of his own department. The secretary of Ireland has seldom an easy task; Stanley found it one of peculiar difficulty. The country was in a very unsettled state. The just concession that had been somewhat tardily yielded a short time before in Catholic emancipation had excited the people to make all sorts of demands, reasonable and unreasonable. As one result of that concession these demands were now permitted to be urged on the floor of the House by the most eloquent and the most widely popular representative Ireland has ever possessed,—one, too, whose hatred of the "base, bloody, and brutal Whigs" seems to have totally unfitted him for judging Whig measures fairly. Problems of great practical difficulty in connection with the land and the church pressed for solution; and the alarming increase of agrarian outrages demanded even more urgently the instant application of vigorous measures of repression. Mr Stanley's conduct in these trying circumstances showed that he had the spirit that rises with difficulties. Undaunted by the fierce denunciations of O'Connell, who styled him Scorpion Stanley, he discharged with determination the ungrateful task of carrying a Coercion Bill through the House. Parliament has probably seldom witnessed warmer or more personal encounters than those which took place about this time between the Liberator and the Irish Secretary, and seldom has an official position been more gallantly defended. It was generally felt that O'Connell, powerful though he was, had fairly met his match in Stanley, who, with invective scarcely inferior to his own, evaded no challenge, ignored no argument, and left no taunt unanswered. The title "Rupert of Debate" is peculiarly applicable to him in connection with the fearless if also often reckless method of attack he showed in his parliamentary war with O'Connell. It was first applied to him, however, thirteen years later by Sir Edward Bulwer Lytton in the following passage of *The New Timon*.—

"One after one the lords of time advance,
Here Stanley meets—here Stanley scorns the glance!
The brilliant chief, irregularly great,
Frank, haughty, rash,—the Rupert of debate."

The best answer, however, which he made to the attacks

of the great agitator was not the retorts of debate, effective though these were, but the beneficial legislation he was instrumental in passing. Two of his measures deserve special mention. He introduced and carried the first national education act for Ireland, one result of which was the remarkable and to many almost incredible phenomenon of a board composed of Catholics, Episcopalians, and Presbyterians, harmoniously administering an efficient education scheme. He was also chiefly responsible for the Irish Church Temporalities Act, though the bill was not introduced into parliament until after he had quitted the Irish secretaryship for another office. By this measure two archbishoprics and eight bishoprics were abolished, and a remedy was provided for various abuses connected with the revenues of the church. As originally introduced, the bill contained a clause authorizing the appropriation of surplus revenues to non ecclesiastical purposes. This had, however, been strongly opposed from the first by Stanley, and several other members of the cabinet, and it was withdrawn by the Government before the measure reached the Lords. There was therefore no ground for the charge of inconsistency brought against Stanley, when a year later he seceded from the cabinet on the proposal being renewed.

In 1833, just before the introduction of the Irish Church Temporalities Bill, Stanley had been promoted to be secretary for the colonies with a seat in the cabinet. In this position it fell to his lot to carry through parliament a measure which is one of the abiding glories of English legislation. The agitation for the emancipation of the slaves had been mainly the work of others whose names have become historical in connection with it; but to Stanley belonged the honour and privilege of bringing it to a successful practical issue in the pages of the statute book. The speech which he delivered on introducing the bill for the emancipation of the slaves in the West Indies, on the 14th May 1833, was one of the finest specimens of his eloquence. It showed a philanthropic spirit and a love of freedom which proved him to be a not unworthy associate of Clarkson, Wilberforce, and Buxton, and it was admirable for the clear statement of the somewhat complicated arrangement by which the all but unanimous wish of the nation was to be carried out. The latter quality was still more conspicuous in committee, through which Stanley carried the measure with the firmness and tact of true statesmanship.

It has already been said that the Irish Church question determined more than one turning-point in Mr Stanley's political career. The most important occasion on which it did so was in 1834, when the proposal of the Government to appropriate the surplus revenues of the church to educational purposes led to his secession from the cabinet, and, as it proved, his complete and final separation from the Whig party. In the former of these steps he had as his companions Sir James Graham, the earl of Ripon, and the duke of Richmond. Soon after it occurred, O'Connell, amid the laughter of the House, described the secession in a couplet from Canning's *Loves of the Triangles* :—

"Still down thy steep, romantic Ashbourne, glides
The Derby dilly carrying six insides."

Stanley was by no means content with marking his disapproval of the conduct of the Government of which he had been a member by the simple act of withdrawing from it. He spoke against the bill to which he objected with a vehemence that showed the strength of his feeling in the matter, and against its authors with a bitterness that he himself is understood to have afterwards admitted to have been unseemly towards those who had so recently been his colleagues. The language of one speech deserves to be quoted as a good specimen of what he could do in the way

of invective when he chose. "Plunder," a term very familiar in more recent debates on the same long-vexed question, was perhaps the mildest word he used. The course followed by the Government was "marked with all that timidity, that want of dexterity, which led to the failure of the unpractised shoplifter." His late colleagues were compared to "thimble-riggers at a country fair," and their plan was "petty larceny, for it had not the redeeming qualities of bold and open robbery."

In the end of 1834, Lord Stanley, as he was now styled by courtesy, his father having succeeded to the earldom in October, was invited by Sir Robert Peel to join the short-lived Conservative ministry which he formed after the resignation of Lord Melbourne. Though he declined the offer for reasons stated in a letter published in the Peel memoirs, he acted from that date with the Conservative party, and on its next accession to power, in 1841, he accepted the office of colonial secretary, which he had held under Lord Grey. His position and his temperament alike, however, made him a thoroughly independent supporter of any party to which he attached himself. When, therefore, the injury to health arising from the late hours in the Commons led him in 1844 to seek elevation to the Upper House in the right of his father's barony, Sir Robert Peel, in acceding to his request, had the satisfaction of at once freeing himself from the possible effects of his "candid friendship" in the House, and at the same time greatly strengthening the debating power on the Conservative side in the other. If the premier in taking this step had any presentiment of an approaching difference on a vital question, it was not long in being realized. When Sir Robert Peel accepted the policy of free trade in 1846, the breach between him and Lord Stanley was, as might have been anticipated from the antecedents of the latter, instant and irreparable. Lord Stanley at once asserted himself as the uncompromising opponent of that policy, and he became, as his position warranted, the recognized leader of the Protectionist party, having Lord George Bentinck and Mr Disraeli for his lieutenants in the Commons. They did all that could be done in a case in which the logic of events was against them, but their watchword of Protection was never to become more than a watchword. It is one of the peculiarities of English politics, however, that a party may come into power because it is the only available one at the time, though it may have no chance of carrying the very principle to which it owes its organized existence. Such was the case when Lord Derby, who had succeeded to the earldom on the death of his father in June 1851, was called upon to form his first administration in February 1852. He was in a minority, but the circumstances were such that no other than a minority Government was possible, and he resolved to take the only available means of strengthening his position by dissolving parliament and appealing to the country at the earliest opportunity. The appeal was made in autumn, but its result did not materially alter the position of parties. Parliament met in November, and by the middle of the following month, the ministry had resigned in consequence of their defeat on the clever but financially unsound budget proposed by Mr Disraeli. For the six following years, during Lord Aberdeen's "ministry of all the talents" and Lord Palmerston's premiership, Lord Derby remained at the head of the opposition, whose policy gradually became more generally Conservative and less distinctively Protectionist as the hopelessness of reversing the measures adopted in 1846 made itself apparent to all but the most reactionary. In 1855, he was asked to form an administration after the resignation of Lord Aberdeen, but failing to obtain sufficient support, he

declined the task. It was in somewhat more hopeful circumstances that, after the defeat of Lord Palmerston on the Conspiracy Bill in February 1858, he assumed for the second time the reins of government. Though he still could not count upon a working majority, there was a possibility of carrying on affairs without sustaining defeat, which was realized for a full session, owing chiefly to the dexterous management of Mr Disraeli in the Commons. The one rock ahead was the question of Reform, on which the wishes of the country were being emphatically expressed, but it was not so pressing as to require to be immediately dealt with. During the session of 1858 the Government contrived to pass two measures of very considerable importance, one a bill to remove Jewish disabilities, and the other a bill to transfer the government of India from the East India Company to the Crown. Next year the question of parliamentary reform had to be faced, and, recognizing the necessity, the Government introduced a bill at the opening of the session, which, in spite of, or rather in consequence of, its "fancy franchises," was rejected by the House, and, on a dissolution, rejected also by the country. A vote of no confidence having been passed in the new parliament on the 10th June, Lord Derby at once resigned.

After resuming the leadership of the Opposition Lord Derby devoted much of the leisure the position afforded him to the classical studies that had always been congenial to him. It was his reputation for scholarship as well as his social position that had led in 1852 to his appointment to the chancellorship of the university of Oxford, in succession to the duke of Wellington; and perhaps a desire to justify the possession of the honour on the former ground had something to do with his essays in the field of authorship. These were made at first with a diffidence that contrasted strongly with his boldness in politics. His first venture was a poetical version of the 9th ode of the 3rd book of Horace, which appeared in Lord Ravensworth's collection of translations of the *Odes*. In 1862 he printed and circulated in influential quarters a volume entitled *Translations of Poems Ancient and Modern*, with a very modest dedicatory letter to Lord Stanhope, and the words "Not published" on the title-page. It contained, besides versions of Latin, Italian, French, and German poems, a translation of the first book of the *Iliad*. The reception of this volume was such as to encourage him to proceed with the task he had chosen as his *magnum opus*, the translation of the whole of the *Iliad*, which accordingly appeared in 1864. The fact that it speedily passed through six editions is, of course, not so unequivocal a proof of its literary merit as would have been the case had the work proceeded from an author of less social distinction, but it has considerable significance. Tried on its merits, the most severe critic could not pronounce the work a failure. That it was not a complete success was due principally to the facts that the author had not caught the difficult secret of the management of the metre he chose—blank verse,—and that he was unable to divest himself of the diffuseness and of the modern cast of thought and style of expression natural to the parliamentary orator.

During the seven years that elapsed between Lord Derby's second and third administrations an industrial crisis occurred in his native county, which brought out very conspicuously his public spirit and his philanthropy. The destitution in Lancashire, caused by the stoppage of the cotton-supply in consequence of the American civil war, was so great as to threaten to overtax the benevolence of the country. That it did not do so was probably due to Lord Derby more than to any other single man. From the first he was the very life and soul of the movement for relief. His personal subscription, munificent though

it was, represented the least part of his service. His noble speech at the meeting in Manchester in December 1872, where the movement was initiated, and his advice at the subsequent meetings of the committee, which he attended very regularly, were of the very highest value in stimulating and directing public sympathy. His relations with Lancashire had always been of the most cordial description, notwithstanding his early rejection by Preston; but it is not surprising that after the cotton famine period the cordiality passed into a warmer and deeper feeling, and that the name of Lord Derby is still cherished in most grateful remembrance by thousands of the factory operatives.

On the rejection of Earl Russell's Reform Bill in 1866, Lord Derby was for the third time intrusted with the formation of a cabinet. Like those he had previously formed it was destined to be short-lived, but it lived long enough to settle on a permanent basis the question that had proved fatal to its predecessor. The "education" of the party that had so long opposed all reform to the point of granting household suffrage was the work of another; but it is understood that Lord Derby fully concurred in, if he was not the first to suggest, the statesmanlike policy by which the question was disposed of in such a way as to take it once for all out of the region of controversy and agitation. The passing of the Reform Bill was the main business of the session 1867. The chief debates were, of course, in the Commons, and Lord Derby's failing powers prevented him from taking any large share in those which took place in the Lords. His description of the measure as a "leap in the dark," was eagerly caught up, because it exactly represented the common opinion at the time,—the most experienced statesmen, while they admitted the granting of household suffrage to be a political necessity, being utterly unable to foresee what its effect might be on the constitution and government of the country.

Finding himself unable, from declining health, to encounter the fatigues of another session, Lord Derby resigned office early in 1868. The step he had taken was announced in both houses on the evening of the 25th February, and warm tributes of admiration and esteem were paid by the leaders of the two great parties. He was succeeded by Mr Disraeli, to whom he yielded the entire leadership of the party as well as the premiership. His subsequent appearances in public were few and unimportant. It was noted as a consistent close to his political life that his last speech in the House of Lords should have been a denunciation of Mr Gladstone's Irish Church Bill marked by much of his early fire and vehemence. A few months later, on the 23rd October 1869, he died at Knowsley.

Lord Derby was one of the last and most brilliant representatives of a class which seems to have become extinct, for the time at least, if the sharp differentiation of human pursuits that has now established itself has not rendered it impossible that it should ever again exist. Politics is now a distinct and exclusive profession; the number of those to whom, like Lord Derby, it is the main without being the all-absorbing interest of life seems to become fewer year by year. There still remain one or two noted statesmen who are also noted authors, but of the life of many interests embracing public affairs, scholarship, literature, society, sportsmanship, and estate management, Lord Derby was almost the last specimen. Of another class, which will have ceased to exist when one or two more have passed away, he was also among the last and best; he was a master of the all but lost art of parliamentary oratory. On this point it is enough to quote the testimony of two most competent witnesses. Sir Archibald Alison, writing of him when he was in the zenith of his powers, styles him "by the admission of all parties the most per-

fect orator of his day.' Even higher was the opinion of Lord Aberdeen, who is reported by the *Times* to have said that no one of the giants he had listened to in his youth, Pitt, Fox, Burke, or Sheridan, "as a speaker, is to be compared with our own Lord Derby, when Lord Derby is at his best." (w. B. S.)

DEREYEH, or DERAYA, a town of Arabia in the Nejd, on the caravan-route from the Red Sea to the Persian Gulf, about 15 miles west of Riad. It was formerly the capital of the Wahabees, and had a population of about 30,000 inhabitants: but it has never recovered from the ruin inflicted on it by the army of Ibrahim Pasha in 1818.

DERHAM, WILLIAM (1657–1735), an eminent English divine and natural philosopher, was born at Stoughton, near Worcester, in 1657. He received his early education at Blockley, in his native county, and in 1679 graduated with much distinction at Trinity College, Oxford. Three years later he became vicar of Wargrave, in Berkshire; and in 1689 he was preferred to the living of Upminster, in Essex. In 1696 he published his *Artificial Clockmaker*, which went through several editions. The best known of his subsequent works are *Physico-Theology*, published in 1713; *Astro-Theology*, 1714; and *Christo-Theology*, 1730. In consideration of these contributions to science and theology he was, in 1716, made a canon of Windsor: and in 1730 he received the degree of D.D. from Oxford. His last work, entitled *A Defence of the Church's Right in Leaschold Estates*, appeared four years previous to his death, which happened in 1735. Besides the works published in his own name, Derham contributed a variety of papers to the *Philosophical Transactions*, revised the *Miscellanea Curiosa*, edited the correspondence of John Ray, and Albin's *Natural History*, and published some of the MSS. of Hooke, the natural philosopher.

DERVISH is a Persian word meaning "the sill of the door," or those who beg from door to door. The Arabic equivalent is fakir, or fuqeer. The dervishes of the Turkish empire may be said to constitute the regular religious orders, and are distinguished from the ulemas, or secular clergy. In Turkey, Egypt, Persia, Hindustan, and Central Asia, however, dervishes, or fakirs, are to be found in great number who belong to no society, but are simply mendicants or single devotees, many of whom subsist by professional jugglery. Especially is this true of the Byragis, the Dundis, the Bhukshooks, the Wanuprusts, the Sunyasis, the Aghorpunts, the Gosiens, the Jogis, the Oodassis, the Jutis, and the Lingaet Jnngums of northern Hindustan, and still more emphatically of the Bonzes, or Buddhist monks. But in the more favourable sense of the word, the dervishes represent Sufism, or the spiritual and mystic side of Islam. Long before the time of Mahomet, Arabic thought was divided, as if by Greek and Indian influences, into the schools of the Meschafounas (the walkers) and the Ischrachafounas (the contemplators). When the Koran appeared, these became the Mutakelims (metaphysicians), and the Sofis (mystics). The latter put an esoteric interpretation on both the Koran and the Hadisât, or collected sayings of the Prophet: they dispense with the jemaat and other formalities of the mosque; they in many cases recognize the fact of spiritual religion outside Islam: and in general they observe the rules of poverty, abstinence from wine, and celibacy. The name fakir, indeed, comes from the saying of the Prophet, "El fakr fakhr," poverty is my pride. The six Erkiân, or pillars of the Tesavvuf, or spiritual life, are (1) the existence of God, (2) His unity, (3) the angels, (4) the prophets, (5) the day of resurrection, and (6) good and evil through God's predestination. But it is only the Tarikats, or orders (lit. paths), among the more orthodox or Sunnite Mahometans who attach much importance to positive dogma. The

Shiite party, especially the Persian dervishes, who trace their descent through various sheikhs and peers from Ali, the fourth caliph, believe that "the paths leading to God are as many as the breaths of his creatures." These form the great majority of the orders; for it is stated in a work called the *Silsileh ul Eulia Ullah* (Genealogy of the Saints of God), last edited in 1783, that, out of 36 well-defined orders, 12 of which were in existence before the beginning of the Ottoman empire, only 3, viz., the Bestamis, the Nakshibendis, and the Bektashis, are descended from the congregation of Abu Bekr, the second caliph, and that all the others are descended from the caliph Ali. As the dervishes do not recognize the legal exposition which the ordinary tribunals give of the letter of the Koran, and acknowledge no authority but that of their spiritual guide, or of Allah himself speaking directly to their souls, the Ottoman sultans have always regarded them with jealousy: and in 1826 Mahmoud entirely suppressed the order of the Bektashis, which had for centuries been closely connected with the Janissaries, or Hoo Keshans (him scatterers), and which is said to have formed part of a Freemason (freemasonry) extending through Palestine, Syria, and Turkey.¹ The other orders, however, or most of them, have survived to the present day, and are generally popular,—one of them, the Merlevis, being joined by persons from the highest and wealthiest ranks. But membership, when it does not proceed beyond the first stage of Shi'at or Sher'iat, i.e., legal religion under the supervision of a murshid,² may be satisfied by the repetition of a few prayers at home and the wearing of the sacred cap for a few minutes each day.

The regular dervishes live in tekkihs, khanakahs, or convents, which are endowed with lands or wakf, just as the Mnths of Hindustan are endowed with *enam* lands, incapable of mortgage or alienation. Thus, in 1634, the sultan Amurath IV. gave to the Bektashis of Konieh the whole tribute paid by that city. Over each convent presides a sheikh, or murshid, who represents the pir, or original founder of the order. This corresponds to the mohunt, malik, or guru of Hindustan. Among the Persian Nosairis (who consider Mahomet an impostor, and perform no ablutions), the succession of sheikhs is hereditary—elsewhere by seniority or election, confirmed by the Sheikh ul Islam. In Hindustan the selection takes place in a *dusname*, or council of mohunts, called among the Sikhs a *muta*. The murid, or disciple, has to undergo a long initiation (called in Turkey *Ikhar*, in Egypt *Ahd*) before he obtains the tayband, or woollen belt, with its pelenk or cabalistic "stone of contentment": the mengusay, or earrings shaped like the horse shoe of Ali; the khirka, or mantle: the tesbeeh, or rosary, containing the ismi-jelal, or the 99 beautiful names of God: and finally the taj, or white cap, with the proper number of terks, or sections, belonging to the order. Similar distinctions are preserved in Hindustan by the barbarous method of marking on the forehead the sandal-wood stripes of Siva, or the white and red trident of Vishnu. In the Merlevi order the murid goes through 1001 days of menial labour, and is during that time called the karra kolak, or jackal. It is not necessary, however, to give up one's private property: and many dervishes are permitted to remain in trade on the

¹ This jealousy was not without foundation. The great political factions which disturbed Constantinople, the Reds, the Whites, the Masked, the Intimates, the Interpreters, the Hashashins (from Hashish, whence assassins), were to some extent connected with the dervish orders. The Kalandaris, founded by an Andalusian dervish who was expelled from the Bektashis, furnished several pretenders to the title of Mehdee, the 12th imam, whose second coming is looked for by all the mystics.

² The subsequent stages are Tarikat, mystical rites, Mevriyat, knowledge, and Hakikat, truth.

principle stated by the Prophet, that "the seeker of gain is the friend of God." Some also are permitted to marry, just as among the Sikh fakirs of Nanuk those named Bashara (with the law), or Sahk (travellers), are allowed to marry and to move about, those named Beshara (without the law), or Majzub (the abstracted), are condemned to celibacy and seclusion. But their lives are mainly directed to the production in themselves of the ecstatic state in which the soul enters the Alem-i-misal, or world of dreams, and becomes one with God. This part of Sofism strongly resembles Vedantism. Kaif, or quiescence, is often caused by the use of hashish (the Arabic khoshkhosh, sold at Constantinople in pastilles called *esrar*), or by khalwet, retirement, and the erba'in, or fast for 40 days. Then they indulge in excessive and rapid repetitions of particular phrases, as the Esami Nahî, or seven attributes of God, viz.—La ilaha ill' Allah (no God but Allah), Ya Allah (O God), Ya Hoo (O Him), Ya Hakk (O just God), Ya Hay (O living God), Ya Kayyoom (O living God), Ya Kahhar (O revenging God). The Zikr consists mainly in a chant, always becoming louder and more violent, of the first attribute; thus—

This leads to the Devr, or rotation, in which the Rufai, or Howling Dervishes, stand in a circle, shoulder to shoulder, each on his right foot, and swaying the body and the left leg backwards and forwards or from side to side, the Sem'a of the Mevlevîs, or Spinning Dervishes, in which a pirouette is performed all round the khaneh on the left heel, the eyes being closed, the arms outstretched, and other more violent dances, accompanied by the music of the nay, or flute, and tambourine, and by the cries of the dancers. In the Halet, or final ecstasy, the dervishes take hold of red-hot implements, place glowing charcoal in the mouth, and exhibit prodigies of muscular strength, which are in some cases the genuine and interesting effects of excitement, in others mere calculated imposture. At last the Jezbed, or attraction of God, begins to operate. Besides daily readings from the Koran, an infinity of small figurative prayers, or terjumans, is repeated. These are connected with the kharika, the palenk, the postaki, or seat, the seggadeh, or carpet, and with almost every act and motion of the dervish within the monastery. A rabouta, or silent prayer, is also practised. In return for these mystical rites the dervish obtains spiritual powers, of which the most remarkable is that called fascination, kuvveh iradat, the power of the will, which depends on certain physical conditions, and seems to include prophecy and the phenomena of mesmerism. By rîsk, or the science of numbers, a charm, composed of the names of the matloob, or patient, and the arif, or knowing person (each letter of the alphabet has a numerical value), is placed on the knee of the latter, and by diligent blowing and mental concentration he is able to summon before him the spirit of the matloob. Some dervishes cure diseases, sell talismans, called tilsims and nushkas, charm snakes, and some are musicians and dancers. It is in Egypt and Hindustan that the extreme degrees of squalor, of imposture, and also of self-mortification are found. Some spend their lives in absolute nakedness, their bodies smeared with wood ash, their unkempt hair twisted into a turban; some roll head over heels for hundreds of miles; some contemplate the tip of the nose from 84 different postures; some live by the fraudulent sale of drugs or by feats of legerdemain. All Mahometan dervishes hold a powerful belief in the perpetual agency of the evlia, or saints, and the departed salihin (pure ones), the "unseen men or masters of destiny," who are sent forth from the kuth, or centre of the roof of the

Kaaba, to control the spiritual affairs of the world. This is closely connected with the doctrine of tenassuh, or metempsychosis, which, however, is held chiefly in a spiritual sense. The Bektashis believe that every one has a mesal, or equal (doppel-gänger?), who watches over him from the unseen region.

For an account of dervishes in Persia, where mysticism has been refined by the poetry of Jelaleddin, Saadi, and Hafiz, and where the seven original orders of Hululieh, Itihadiieh, Vafsoohieh, Ashkieh, Telkinieh, Zunkieh, Wahdetieh, are still preserved, see Malcolm's *History of Persia*, and De Gobineau's *Three Years in Asia*, 1859; for Central Asia, the works of Vambéry and other travellers; for Hindustan, *The Peoples of India*, by Kaye and Watson, 1868-72, and Steel's *Hindu Castes*. For Egypt, where four orders are presided over by the Sheikh el Bekri, and where the ceremony of the Doseh, or the mounted sheikh riding over the bodies of the dervishes, is still practised, see Lane's *Modern Egyptians*, and for the general subject, *The Dervishes, or Oriental Spiritualism*, by J. P. Brown, Constantinople, 1868, which contains a number of valuable translations of Dervish MSS (W C S.)

DESAIX DE VOYGOUX, LOUIS CHARLES ANTOINE (1768-1800), one of the most eminent generals of the French republic, was born at the Chateau d'Ayat, near Riom, in Auvergne, on the 17th August 1768. He studied at the military school founded by the Marshal d'Effiat, and distinguished himself by his eagerness in acquiring a knowledge of his chosen profession. After joining the army he spent some time in garrison at Brancion and Huningue. He was favourable to the Revolution, but was an object of suspicion to the Convention, on account of his aristocratic birth and his popularity with his men. He was twice suspended, and on the earlier occasion he was imprisoned for two months by order of Carnot. The first engagement in which he took part was the battle of Lauterburg, in which he was wounded; and when Moreau executed his masterly retreat through the Black Forest, Desaix contributed not a little to the success of that memorable exploit. After some gallant achievements, such as the repulse of the Archduke Charles at Rastadt, and the defence of the bridge of Kehl, he accompanied Bonaparte (1798-9) to Egypt, where he dispersed the Arabs and for his various services was made commander of Upper Egypt. The campaign of eight months in which he completed the conquest of Upper Egypt was the great achievement of his military career. During his occupation he conducted himself in such a way as to win from the inhabitants the title of the Just Sultan, and to be compared by his soldiers to Bayard. On his return to Europe he found Napoleon marching to the conquest of Italy. With a small squadron he hastened to join the first consul, whom he overtook at Marengo at the very moment when the Austrians had deemed themselves secure of the victory. His timely arrival changed the fortune of the day; but in the moment of victory he was shot through the heart and immediately expired, 14th June 1800. His body was embalmed at Milan, and finally deposited in the convent of Mount St Bernard, where a handsome monument is erected to his memory.

DESAUGIERS, MARC ANTOINE MADELEINE (1772-1827), a French dramatist and song-writer, son of Marc Antoine Desaugiers, a musical composer, was born at Fréjus on the 17th November 1772. Being intended for the church, he studied at the Mazarin College in Paris, where he had for one of his teachers the celebrated critic Geoffroy. He did not continue his studies long, however, having shown signs of a decided dramatic talent, which his father thought it well to encourage. Ere he completed his twentieth year he had written a comedy in verse in one act, which was well received when produced on the stage in 1792. In the following year he wrote some verses which appeared in the *Almanach des Muses*. During the stormy period of the Revolution he emigrated to St Domingo with a sister who was about to marry a creole

planter. He found that he had only escaped one danger for another equally great. During the negro revolt he was made prisoner, and barely escaped with his life. He took refuge in the United States, where he supported himself by teaching the piano. In 1797 he returned to his native country, and at once commenced to write for the stage. He was successful from the first, and in a very few years he became famous as a writer of comedies, operas, and vaudevilles, which were produced in rapid succession at the Théâtre des Variétés and the Vaudeville. During the same period he acquired a reputation of a still higher kind as a writer of convivial and satirical songs, which, though different in character, can only worthily be compared with those of Beranger. His singing of his own songs made his society eagerly sought for in many of the salons of Paris. In 1815 Desaugiers succeeded Barré as manager of the Vaudeville, and he was prosperous for some years, though not in all respects well-fitted for the position. In 1820, however, the opposition of the Gymnase proved too strong for him, and he resigned. Five years later he allowed himself to be persuaded to resume the position, but he had scarcely done so when he fell into bad health. He died in Paris of the result of an operation for stone on the 9th August 1827.

An edition of Desaugier's *Chansons et poésies diverses* appeared in three volumes in 1827. It contains a notice of his life by Brazier. See also Saint Beuve's *Portraits Contemporains*.

DESAULT, PIERRE JOSEPH (1744–95), a distinguished French anatomist and surgeon, was born at Magny-Vernais, a village of Franche-Comté, in 1744. He was descended of humble parents, and received the early part of his education in a school of the Jesuits, being destined for the church. His own inclination, however, tended to the study of medicine; and, after learning something from the barber-surgeon of his native village, he was at length settled as an apprentice in the military hospital of Belfort. Here he acquired some knowledge of anatomy and military surgery; and, having previously made considerable progress in mathematical studies, he applied this knowledge, after the example of Borelli and others, to the investigation of physiological subjects. He early translated Borelli's *De Motu Animalium*, and added notes and illustrations, which, although founded on wrong principles, gave undeniable proofs of zeal and industry.

He went to Paris when about twenty years of age, and opened a school of anatomy in the winter of 1766, which was soon attended by about 300 pupils, a great proportion of whom were older than himself. His success excited the jealousy of the established teachers and professors, who, although he was patronized and protected by some surgeons of great eminence, would have obliged him to renounce public teaching, had he not resorted to the expedient of adopting the name of another as a sanction to his proceedings. In 1776 he was admitted a member of the corporation of surgeons; and so limited were his finances at this time, that he was allowed to pay his fees at his own convenience. He successively held the positions of honour in the corporation and academy of surgery, and in 1782 he was appointed surgeon-major to the hospital *De la Charité*.

Desault was now regarded as one of the first surgeons of Paris. He succeeded to the next vacancy at the Hôtel Dieu; and, after the death of Moreau, almost the whole surgical department of that hospital was intrusted to him. He instituted a clinical school of surgery there on a liberal and extensive plan, which attracted a great concourse of students, not only from every part of France, but also from other countries. He frequently had an audience of about 600; and most of the surgeons of the French army derived their knowledge from his lectures. He introduced many improvements into the practice of

surgery, as well as in the construction of various surgical instruments.

In 1791 he published a work entitled *Journal de Chirurgie*, edited by his pupils, which was a record of the most interesting cases that had occurred in his clinical school, with the remarks which he had made upon them in the course of his lectures. But in the midst of his valuable labours he became obnoxious to some of the Revolutionists, and he was, on some frivolous charge, denounced to the popular sections. After being twice examined, he was seized on the 28th May 1793, while delivering a lecture, carried away from his theatre, and committed to the prison of the Luxembourg. In three days, however, he was liberated, and permitted to resume his functions. When the school of health was established, he was appointed clinical professor for external maladies; and it was through his means that the Evêché was converted into an hospital for surgical operations. He died on the 1st June 1795 of an ataxic fever, which he had caught two days previously while attending the dauphin in the Temple. An opinion was prevalent among the populace that he was poisoned because he had refused to do anything against the dauphin's life. The autopsy which was held went to disprove the story, but it shows the opinion the public entertained of Desault's integrity. A pension was settled on his widow by the republic. The only work of which he is the sole author is entitled *Traité des Maladies Chirurgicales, et des Opérations qui leur conviennent*, in 2 vols 8vo.

See Petit's *Éloge de Desault* (Lyons, 1795).

DESCARTES, RENÉ, was born at La Haye, in Touraine, on the 31st of March 1596, and died at Stockholm on the 11th of February 1650. The small town of La Haye lies on the right bank of the Creuse, about midway between Tours and Poitiers. The house is still shown where he was born, and a *métairie* about three miles off still retains the name of Les Cartes. His family on both sides was of Poitevin descent, and had its head-quarters in the neighbouring town of Châtelleraut, where his grandfather had been a physician. Joachim Descartes, his father, having purchased a commission as counsellor in the Parlement of Rennes, introduced the family into that demi-noblesse of the robe, which, in stately isolation between the bourgeoisie and the high nobility, maintained a lofty rank in the hierarchy of France. For the one half of each year required for residence the elder Descartes removed with his wife, Jeanne Brochard, to Rennes. Three children, all of whom first saw the light at La Haye, sprung from the union—a son who afterwards succeeded to his father in the Parlement, a daughter who married a M. du Crevis, and a second son René. His mother, who had been ailing beforehand, never recovered from her third confinement, and the motherless infant was entrusted to a nurse, whose care Descartes in after years remembered by a small pension.

Descartes, who in the family circle was known as Du Perron, from a small estate destined for his inheritance, soon showed, say the chroniclers, an inquisitive mind, which made his father style him his philosopher. He was sent off at the age of eight to the school of La Flèche, which Henry IV. had lately founded and endowed for the Jesuits, and there he continued from 1604 to 1612. Of the education there given, of the equality maintained among the pupils, and of their free intercourse, Descartes at a later period spoke in terms of high praise.¹ He himself enjoyed exceptional privileges, his feeble health excused him from the morning duties, and thus early he acquired the habit of matutinal reflection in bed, which clung to him through-

¹ Œuvres (ed. Cousin), viii. 546.

For an instant Descartes seems to have concurred in the plan of purchasing a post at Châtellerault, but easily gave up the idea, and settled in Paris (June 1625), in the quarter where he had sought seclusion before. By this time he had ceased to devote himself to pure mathematics, and in company with his friends Mersenne and Mydorge was deeply interested in the theory of the refraction of light, and in the practical work of grinding glasses of the best shape suitable for optical instruments. But all the while his aim was fixed on something beyond either mathematics or physics; he was engaged with reflections on the nature of man, of the soul, and of God; and it need cause no surprise that Descartes for a while remained invisible even to his most familiar friends. But their importunity made a hermitage in Paris impossible; and a graceless friend surprised the philosopher in bed at 11 o'clock in the morning meditating on some problem, and occasionally taking notes. In disgust at the apparent hopelessness of the position for a student, Descartes started for the west to take part in the siege of La Rochelle, and entered the famine-stricken city with the victorious troops on the 30th October 1628. A meeting at which he was present after his return to Paris decided his vocation. He had expressed an opinion that the true art of memory was not to be gained by technical devices, but by a philosophical apprehension of things; and the Cardinal de Berulle, the founder of the Congregation of the Oratory, was so struck by the tone of the remarks as to impress upon the speaker the duty of spending his life in the examination of truth. Descartes accepted the philosophic mission. In the end of 1628 he left Paris, and in the spring of 1629 he settled in Holland. His financial affairs he had intrusted to the care of the Abbé Picot, and as his literary and scientific representative he adopted Père Mersenne.

Between the ages of thirty-three and fifty-three (1629-1649) Descartes lived almost entirely in Holland. Thrice only did he revisit France during that period—in 1644, 1647, and 1648. The first of these occasions was in order to settle family affairs after the death of his father in 1640. The eldest brother seems to have been disposed to take all he could, and to have expected the philosopher to be yielding in money matters. So little notice did the family think it necessary to take of a brother who had sunk to the level of literature, that a letter of René to his father, affectionately excusing his long absence, reached Rennes only after that father was lying in the tomb. The second brief visit, in 1647, partly on literary, partly on family business, was signalized by the award of a pension of 3000 francs, obtained from the royal bounty by Cardinal Mazarin in consideration of the advantages which Descartes's investigations conferred upon mankind, and to aid him in continuing his experiments. The pension was punctually paid. The last visit in 1648 was less fortunate. A royal order summoned him to France for new honours—an additional pension and a permanent post—for his fame had by this time gone abroad, and it was the age when princes sought to attract genius and learning to their courts. But when Descartes arrived, he found Paris rent asunder by the civil war of the Fronde. He paid the costs of his royal parchment, and left for his Dutch home without a word of reproach. The only other occasions on which he was out of the Netherlands were in 1630, when he made a flying visit to England to observe for himself some alleged magnetic phenomena, and in 1634, when he took an excursion to Denmark.

During his residence in Holland he lived at thirteen different places, and changed his abode twenty-four times. In the choice of these spots two motives seem to have influenced him—the neighbourhood of a university or college,

and the amenities of the situation. Franeker, one of the neatest towns in Friesland, was the seat of a university founded in 1585; Harderwyk contained a venerable gymnasium, of some note in the physical sciences and theology; Deventer possessed a seminary still well endowed, but less famous than it had been in the days of Erasmus;¹ Utrecht acquired a university so late as 1634, and Leyden had a notable one founded in 1575. Amersfoort, where he also lived, seems to be connected with a love affair,—the only one in his life; at least it was there that his daughter Francine died in 1640, at the age of five. Amsterdam, where he often lodged, Leeuwarden in Friesland, and Dort were also residences. He once settled near Utrecht, as well as in the town; but the three spots which seem to have been most attractive were—Endegeest, a country house more than a mile north-west of Leyden, of which Sorbière has given a pleasing description in one of his letters, and the two villages of Egmond op den Hoef and Egmond the Abbey, situated between Zaandam and the ocean, in one of the prettiest localities of North Holland.

The time thus spent seems to have been on the whole happy, even allowing for some warm discussions with the mathematicians and metaphysicians of France, and for some harassing controversies in the Netherlands. Friendly agents—chiefly Catholic priests—were the intermediaries who forwarded from Dort, Haarlem, Amsterdam, and Leyden his correspondence to his proper address, which he wished kept completely secret, and Father Mersenne was only too willing to send him loads of objections and questions. During the first twenty years of his life his health had been weak² and his complexion pale. After that time the disease in his frame seems to have worked itself off, not without some effervescence. This is the period of his camp life (duc, as he himself says, to "heat in the liver"),³ of his wanderings, enthusiasm, dreams, and vows. With his thirtieth year this struggle seems at an end; his health seems established; and the washed-out vermilion of his prime gives place to a dark olive complexion in his riper manhood. It is touching to hear his delight in the freedom from intruders. "I sleep here ten hours every night," he writes from Amsterdam, "and no care ever shortens my slumber." "I take my walk every day through the confusion of a great multitude with as much freedom and quiet as you could find in your rural avenues."⁴ At his first coming to Franeker he arranged to get a cook acquainted with French cookery; but, to prevent misunderstanding, it may be added that his diet was mainly vegetarian, and that he rarely drank wine. New friends gathered round him who took a keen interest in his researches. Once only do we find him taking an interest in the affairs of his neighbours,—to ask pardon from the Government for a homicide.⁵ He continued the profession of his religion. Sometimes from curiosity he went to the ministrations of anabaptists,⁶ to hear the ranting of peasants and artisans. He carried few books to Holland with him, but a Bible and the *Summa* of Thomas Aquinas were amongst them.⁷ One of the recommendations of Egmond the Abbey was the free exercise there allowed to the Catholic religion. At Franeker his house was a small château, "separated by a moat from the rest of the town, where the mass could be said in safety."⁸ And one motive in favour of accepting an invitation to England lay in the alleged leanings of Charles I. to the older church.

The best account of Descartes's mental history during his life in Holland is contained in his letters, which extend

DESCARTES

over the whole period, and are particularly frequent in the latter half. The majority of them are addressed to Mersenne, and deal with problems of physics and musical theory (in which he took a special interest). Mathematical subjects are a common topic. Several letters between 1643 and 1649 are addressed to the Princess Elizabeth, the eldest daughter of the ejected elector palatine, who lived at the Hague, where her mother maintained the semblance of a royal court. The princess was obliged to quit Holland, but kept up a philosophical correspondence with Descartes. It is to her that the *Principles of Philosophy* were dedicated, and in her alone, according to Descartes, were united those generally separated talents for metaphysics and mathematics which are so characteristically co-operative in the Cartesian system. Two Dutch friends, Zuylichem, the father of the more celebrated Huyghens, and Hoogheland, figure amongst the correspondents, not to mention various savants, professors, and churchmen (particularly Jesuits).

His residence in the Netherlands (1625-1647). Abroad perous and brilliant days of the Dutch state, under the stadtholdership of Frederick Henry (1625-1647). Abroad its navigators monopolized the commerce of the world, and explored unknown seas, at home the Dutch school of painting reached its acme in Rembrandt (1607-1669), and the philological reputation of the country was sustained by Grotius, Vossius, and the elder Heinsius. And yet, though Rembrandt's *Nightwatch* is dated the very year after the publication of the *Meditations*, not a word in Descartes breathes of any work of art or historical learning. The contempt of æsthetics and erudition is characteristic of the most typical members of the Cartesian school, especially Malebranche. Though Descartes probably read more than some of his admirers supposed he was not in any strict sense a reader. His wisdom grew mainly out of his own reflections and experiments, calmly yet ceaselessly pursued. Of mere learning and scholarship he had no esteem. The story of his disgust, when he found that Queen Christina devoted some time every day to the study of Greek under the tuition of Vossius, is at least true in substance.¹ It gives no evidence of science, he remarks, to possess a tolerable knowledge of the Roman tongue, such as once was possessed by the populace of Rome.² In all his travels, and in the different places at which he settled, his interest seems untouched either by art or history, he looks only to the phenomena of nature and the actual aspects of human life. He was a spectator rather than an actor on the stage of the world. If he entered the army, it was merely because the position gave a vantage-ground from which to make his observations. In the political interests which these contests involved he took no part, his favourite disciple, the Princess Elizabeth, was the daughter of the banished king, against whom he had served in Bohemia, and Queen Christina, his second royal follower, was the daughter of Gustavus Adolphus.

In many ways Descartes is a type of that self-reliant, harsh, and abstract spirit of science to which erudition and all the heritage of the past seem but elegant and unworthy trifling. The science of Descartes was physics in all its branches, but especially as applied to physiology. Science, he says, may be compared to a tree; metaphysics is the root, physics is the trunk, and the three chief branches are mechanics, medicine, and morals,—the three applications of our knowledge to the outward world, to the human body, and to the conduct of life.³

Such then was the work, and such the ends, that Descartes had in view in Holland. His residence was generally divided into two parts—one his workshop for

science, the other his reception-room for society. "Here are my books," he is reported to have told a visitor, as he pointed to the animals he had dissected. "I am now," he writes in 1630, "studying chemistry and anatomy together; and every day I learn something which I could not find in books."⁴ He is working hard at his book on refraction, and at the same time is busy dissecting the heads of different animals in order to explain imagination and memory, which he considers physical processes.⁵ It need not from this be supposed that Descartes was a laborious student. "I can say with truth," he writes to the Princess Elizabeth, "that the principle which I have always observed in my studies, and which I believe has helped me most to gain what knowledge I have, has been never to spend beyond a very few hours daily in thoughts which occupy the imagination, and a very few hours yearly in those which occupy the understanding, and to give all the rest of my time to the relaxation of the senses and the repose of the mind." But his expectations from the study of anatomy and physiology went a long way. "The conservation of health," he writes in 1646, "has always been the principle end of my studies."⁷ In 1629 he asks Mersenne to take care of himself "till I find out if there is any means of getting a medical theory based on infallible demonstrations, which is what I am now inquiring."⁸ And to Zuylichem he writes in 1638,—⁹ "I have never taken so much care of myself as at present; and whereas I used to think that death could take from me only thirty or forty years at most, it could not overtake me now without depriving me of the hope of more than a century." And similar views seem to have been expressed by him to Sir Kenelm Digby, who visited him in Holland. Astronomical inquiries in connection with optics, meteorological phenomena, and, in a word, the whole field of natural laws, excited his desire to explain them. His own observation, and the reports of Mersenne, furnished his data. Of Bacon's demand for observation and collection of facts he is an imitator; and he wishes (in a letter of 1632) that "some one would undertake to give a history of celestial phenomena after the method of Bacon, and describe the sky exactly as it appears at present, without introducing a single hypothesis."¹⁰

He had several writings in hand during the early years of his residence in Holland, but the main work of this period was a physical doctrine of the universe which he termed *The World*. Shortly after his arrival he writes to Mersenne that it will probably be finished in 1633, but meanwhile asks him not to disclose the secret to his Parisian friends. Already anxieties appear as to the theological verdict upon two of his fundamental views—the infinitude of the universe, and the earth's rotation round the sun.¹¹ But towards the end of year 1633 we find him writing as follows:¹² "I had intended sending you my *World* as a New Year's gift, and a fortnight ago I was still minded to send you a fragment of the work, if the whole of it could not be transcribed in time. But I have just been at Leyden and Amsterdam to ask after Galileo's cosmical system, as I imagined I had heard of its being printed last year in Italy. I was told that it had been printed, but that every copy had been at the same time burnt at Rome, and that Galileo had been himself condemned to some penalty." He has also seen a copy of Galileo's condemnation at Liège (20th September 1633), with the words—"Although he professes that the (Copernican) theory was only adopted by him as a hypothesis." His friend Beeckman lent him a copy of Galileo's work,

which he glanced through in his usual manner with other men's books, he found it good, and "failing more in the points where it follows received opinions than where it diverges from them"¹ The consequence of these reports of the hostility of the church to the doctrine on which his theory reposed led him to abandon all thoughts of publishing The *World* was consigned to his desk; and although doctrines in all essential respects the same constitute the physical portion of his *Principia*, it was not till after the death of Descartes that fragments of the work, including *Le Monde*, or a treatise on light, and the physiological tracts *L'Homme* and *La Formation du Fœtus*, were given to the world by Clerelier, in 1664. Descartes was not disposed to be a martyr; he had a sincere respect for the church and for authority, and had no wish to shock prejudices, or to begin an open conflict with established doctrines.

In 1636 Descartes had resolved to publish some specimens of the fruits of his method, and some general observations on its nature which, under an appearance of simplicity, might sow the good seed of more adequate ideas on the world and man. "I should be glad," he says, when talking of a publisher,² "if the whole book were printed in good type, on good paper, and I should like to have at least 200 copies for distribution. The book will contain four essays, all in French, with the general title of 'Project of a Universal science, capable of raising our nature to its highest perfection; also Dioptrics, Meteors, and Geometry, wherein the most curious matters which the author could select as a proof of the universal science which he proposes are explained in such a way that even the unlearned may understand them.'" The work appeared anonymously at Leyden (published by Jean Maire) in 1637, under the modest title of *Essais Philosophiques*; and the project of a universal science becomes the *Discours de la méthode pour bien conduire sa raison et chercher la vérité dans les sciences*. In 1644 it appeared in a Latin version, revised by Descartes, as *Specimina Philosophica*. A work so widely circulated by the author naturally attracted attention, but in France it was principally the mathematicians who took it up, and their criticisms were more pungent than complimentary. Fermat, Roberval, and Desargues took exception in their various ways to the methods employed in the geometry, and to the demonstrations of the laws of refraction given in the Dioptrics and the Meteors. The dispute on the latter point between Fermat and Descartes was continued, even after the philosopher's death, as late as 1662. In the virgin soil of the youthful Dutch universities the effect of the Cartesian essays was greater.

The first public teacher of Cartesian views was Henri Renery, a Belgian, who at Deventer and afterwards at Utrecht had introduced the new philosophy which he had learned from personal intercourse with Descartes. Renery only survived five years at Utrecht; and it was reserved for Regius (Henri De Roy),—who in 1638 had been appointed to the new chair of botany and theoretical medicine at Utrecht, and who visited Descartes at Egmond in order more thoroughly to learn his views,—to throw down the gauntlet to the adherents of the old methods. With more eloquence and vigour than judgment or prudence, he pronounced and defended theses bringing into prominent relief the points in which the new doctrines clashed with the old. The attack was opened by Gisbert Voet, foremost among the theological professors and clergy of Utrecht, a preacher of note and a stronghold of orthodoxy. In 1639 he published a series of arguments against atheism, in which the Cartesian views were not obscurely indicated as perilous for the faith, though no name was mentioned. Next year he

persuaded the magistracy to issue an order forbidding Regius to travel beyond the received doctrine; for Regius, contrary to the advice of Descartes, had formulated his view of Cartesianism in the phrase that man was a unity merely by accident, and meddled in his lectures with topics not usually associated with a chair of medicine. The magisterial views seem to have prevailed in the professoriate, which formally in March 1642 expressed its disapprobation of the new and pretended philosophy as well as of its expositors. As yet Descartes was not directly attacked. Voet now issued, through the medium and under the name of Martin Schoock, one of his pupils, a pamphlet with the title of *Methodus novæ philosophiæ Renati Descartes*, in which atheism and infidelity were openly declared to be the effect of the new teaching. Descartes replied to Voet directly in a long and vigorous letter, published at Amsterdam in 1643. Yet notwithstanding, he was summoned before the magistrates of Utrecht to defend himself against charges of irreligion and slander. What might have happened we cannot tell; but Descartes threw himself on the protection of the French ambassador and the prince of Orange, and the city magistrates, from whom he vainly demanded satisfaction in a dignified letter,³ were snubbed by their superiors. About the same time (April 1645) Schoock was summoned before the university of Groningen, of which he was a member, and forthwith disavowed the more abusive passages in his book. So did the effects of the *odium theologicum*, for the meanwhile at least, die away.

In the *Discourse of Method* Descartes had sketched the main points in his new views, with a mental autobiography which might explain their origin, and with some suggestions as to their applications. His second great work, *Meditations on the First Philosophy*, which had been begun soon after his settlement in the Netherlands, expounded in more detail the foundations of his system, laying especial emphasis on the priority of mind to body, and on the absolute and ultimate dependence of mind as well as body on the existence of God. In 1640 a copy of the work in manuscript was despatched to Paris, and Mersenne was requested to lay it before as many thinkers and scholars as he deemed desirable, with a view to getting their views upon its argument and doctrine. Mersenne was not slack in submitting the work to criticism, and Descartes soon had a formidable list of objections to reply to. Accordingly, when the work was published at Paris in August 1641, under the title of *Meditationes de prima philosophiâ ubi de Dei existentia et Animæ immortalitate* (though it was in fact not the *immortality*, but the *immateriality* of the mind, or, as the second edition described it, *animæ humana a corpore distincta*, which was maintained), the title went on to describe the larger part of the book as containing various objections of learned men, with the replies of the author. These objections in the first edition are arranged under six heads:—the first came from Caterus, a theologian of Louvain; the second and sixth are anonymous criticisms from various hands, whilst the third, fourth, and fifth belong respectively to Hobbes, Arnauld, and Gassendi. In the second edition appeared the seventh—objections from Père Bourdin, a Jesuit teacher of mathematics in Paris; and subsequently another set of objections known as those of *Hyperaspistes*, was included in the collection of Descartes's letters. The anonymous objections are very much the statement of common sense against philosophy, those of Caterus criticise the Cartesian argument from the traditional theology of the church, those of Arnauld are an appreciative inquiry into the bearings and consequences of the meditations for religion.

¹ Œuvr. vi. 243² Œuvr. vi. 276³ Œuvr. ix. 250.

and morality; while those of Hobbes and Gassendi—both somewhat senior to Descartes and with a dogmatic system of their own already formed—are a keen assault upon the spiritualism of the Cartesian position from a generally "ecumenical" stand-point. The criticisms of the last two are the criticisms of a hostile school of thought; those of Arnauld are the difficulties of a possible disciple.

In 1644 the third great work of Descartes, the *Principia Philosophiæ*, appeared at Amsterdam. Passing briefly over the conclusions arrived at in the *Meditations*, it deals in its second, third, and fourth parts with the general principles of physical science, especially the laws of motion, with the theory of vortices, and with the phenomena of heat, light, gravity, magnetism, electricity, &c., upon the earth. This work exhibits some curious marks of caution. Undoubtedly, says Descartes, the world was in the beginning created in all its perfection. "But yet as it is best, if we wish to understand the nature of plants or of men, to consider how they may by degrees proceed from seeds, rather than how they were created by God in the beginning of the world, so, if we can excogitate some extremely simple and comprehensible principles, out of which, as if they were seeds, we can prove that stars, and earth, and all this visible scene could have originated, although we know full well that they never did originate in such a way, we shall in that way expound their nature far better than if we merely described them as they exist at present." The Copernican theory is rejected in name, but retained in substance. The earth, or other planet, does not actually move round the sun; yet it is carried round the sun in the subtle matter of the great vortex, where it lies in equilibrium,—carried like the passenger in a boat, who may cross the sea and yet not rise from his berth.

In 1647 the difficulties that had arisen at Utrecht were repeated on a smaller scale at Leyden. There the Cartesian innovations had found a patron in Adrian Heerebord, and were openly discussed in theses and lectures. The theological professors took the alarm at passages in the *Meditations*, an attempt to prove the existence of God, savoured, as they thought, of atheism and heresy. When Descartes complained to the authorities of this unfair treatment,² the only reply was an order by which all mention of the name of Cartesianism, whether favourable or adverse, was forbidden in the university. This was scarcely what Descartes wanted, and again he had to apply to the prince of Orange, whereupon the theologians were asked to behave with civility, and the name of Descartes was no longer proscribed. But other annoyances were not wanting from unfaithful disciples and unsympathetic critics. The *Instantiæ* of Gassendi appeared at Amsterdam in 1644 as a reply to the reply which Descartes had published of his previous objections; and the publication by Regius of his work on Physical Philosophy gave the world to understand that he had ceased to be a thorough adherent of the philosophy which he had so enthusiastically adopted.

It was about 1648 that Descartes lost his friends Mersenne and Mydorge by death. The place of Mersenne as his Parisian representative was in the main taken by Claude Clerselier (the French translator of the *Objections and Responses*), whom he had become acquainted with in Paris. Through Clerselier he came to know Pierre Chanut, who in 1645 was sent as French ambassador to the court of Sweden. Queen Christina, the daughter of the great Gustavus, was not yet twenty, and took a lively, if a somewhat whimsical interest in literary and philosophical culture. Through Chanut, with whom she was on terms

of familiarity, she came to hear of Descartes, and a correspondence which the latter nominally carried on with the ambassador was in reality intended for the eyes of the queen. The correspondence took an ethical tone. It began with a long letter on Love in all its aspects (February 1647),³ a topic suggested by Chanut, who had been discussing it with the queen; and this was soon followed by another to Christina herself on the Chief Good. An essay on the Passions of the Mind (*Passions de l'Âme*), which had been written originally for the Princess Elizabeth, in development of some ethical views suggested by the *De Vita Beata* of Seneca, was inclosed at the same time for Chanut. It was a draft of the work published in 1650 under the same title. Philosophy, particularly that of Descartes, was becoming a fashionable *divertissement* for the queen and her courtiers, and it was felt that the presence of the sage himself was necessary to complete the good work of education. An invitation to the Swedish court was urged upon Descartes, and after much hesitation accepted; a vessel of the royal navy was ordered to wait upon him, and in September 1649 he left Egmond for the north.

The position on which he entered at Stockholm was certainly no sinecure, and utterly unsuited for a man who had always tried to be his own master. The young queen, full of plans and energy, wanted Descartes to draw up a code for a proposed academy of the sciences, and to give her an hour of philosophic instruction every morning at five. And in order to tie him down to the country she had already determined to create him a noble, and begun to look out an estate in the lately annexed possessions of Sweden on the Pomeranian coast. But these things were not to be. His friend Chanut fell dangerously ill; and Descartes, who devoted himself to attend in the sick-room, was obliged to issue from it every morning in the chill northern air of January, and spend an hour in the palace library. The ambassador recovered, but Descartes fell a victim to the same disease—an inflammation of the lungs. The last time he saw the queen was on the 1st of February 1650, when he handed to her the statutes he had drawn up for the proposed academy. Ten days after he was dead. The queen, in her first grief and enthusiasm, would have liked to bury him grandly at the feet of the Swedish kings, and to raise a costly mausoleum in his honour; but these plans were overruled, and a plain monument in the Catholic cemetery was all that marked the place of his rest. Sixteen years after his death the French treasurer D'Alibert made arrangements for the conveyance of the ashes to his native land; and in 1667 they were interred in the church of Ste Geneviève du Mont, the modern Pantheon. In 1819, after being temporarily deposited in a stone sarcophagus in the court of the Louvre during the Revolutionary epoch, they were transferred to St Germain-des-Près, where they now repose between Montfaucon and Mabillon. A monument was raised to his memory at Stockholm by Gustavus III.; and some years ago a statue was erected to him at Tours, with the inscription *Je pense, donc je suis* on the pedestal.

Descartes was never married, and probably had little of the amorous in his temperament. He has alluded to a childish fancy for a young girl with a slight obliquity of vision; but he only mentions it *à propos* of the consequent weakness which led him to associate such a defect with beauty.⁴ Mythical rumours represent him as telling a belle that he found no beauty comparable to the beauty of truth. In person he was a little man, with large head, projecting brow, prominent nose, and eyes wide apart, with black hair coming down almost to his eyebrows. His voice was feeble. He usually dressed in black, with unobtrusive propriety

The end of all study, says Descartes in one of his earliest writings, ought to be to guide the mind to form true and sound judgments on every thing that may be presented to it.¹ The sciences in their totality are but the intelligence of man; and all the details of knowledge have no value save as they strengthen the understanding. The mind is not for the sake of knowledge, but knowledge for the sake of the mind. This is the re-assertion of a principle which the Middle Ages had lost sight of—that knowledge, if it is to have any value, must be intelligence, and not cradition.

But how is intelligence, as opposed to erudition, possible? The answer to that question is the method of Descartes. That idea of a method grew up with his study of geometry and arithmetic,—the only branches of knowledge which he would allow to be “made sciences,” those which the Jesuits best taught, and which he himself cultivated most zealously in early life. But they did not satisfy his demand for intelligence. “I found in them,” he says, “different propositions on numbers of which, after a calculation, I perceived the truth; as for the figures, I had, so to speak, many truths put before my eyes, and many others concluded from them by analogy; but it did not seem to me that they told my mind with sufficient clearness why the things were as I was shown, and by what means their discovery was attained.”² The mathematics of which he thus speaks included the geometry of the ancients, as it had been handed down to the modern world, and arithmetic with the developments it had received in the direction of algebra. The ancient geometry, as we know it, is a wonderful monument of ingenuity—a series of *tours de force*, in which each problem to all appearance stands alone, and, if solved, is solved by methods and principles peculiar to itself. Here and there particular curves, for example, had been obliged to yield the secret of their tangent; but the ancient geometers apparently had no consciousness of the general bearings of the methods which they so successfully applied. Each problem was something unique; the elements of transition from one to another were wanting; and the next step which mathematics had to make was to find some method of reducing, for instance, all curves to a common notation. When that was found, the solution of one problem would immediately entail the solution of all others which belonged to the same series as itself.

The arithmetical half of mathematics, which had been gradually growing into algebra, and had decidedly established itself as such in the *Logistica Speciosa* of Vieta (1540–1603), supplied to some extent the means of generalizing geometry. And the algebraists or arithmeticians of the 16th century, such as Lucas de Borgo, Cardan, and Tartaglia, had used geometrical constructions to throw light on the solution of particular equations. But progress was made difficult, in consequence of the clumsy and irregular nomenclature employed. With Descartes the use of exponents as now employed for denoting the powers of a quantity becomes systematic; and without some such step by which the homogeneity of successive powers is at once recognized, the binomial theorem could scarcely have been detected. The restriction of the early letters of the alphabet to known, and of the late letters to unknown quantities is also his work. In this and other details he crowns and completes, in a form henceforth to be dominant for the language of algebra, the work of numerous obscure predecessors, such as Étienne de la Roche, Stiefel, and others.

Having thus perfected the instrument, his next step was to apply it in such a way as to bring uniformity of method into the isolated and independent operations of geometry.

“I had no intention,” he says in the *Method*,³ of attempting to master all the particular sciences commonly called mathematics; but as I observed that, with all differences in their objects, they agreed in considering merely the various relations or proportions subsisting among these objects, I thought it best for my purpose to consider these relations in the most general form possible, without referring them to any objects in particular except such as would most facilitate the knowledge of them. Perceiving further, that in order to understand these relations I should sometimes have to consider them one by one, and sometimes only to bear them in mind or embrace them in the aggregate, I thought that, in order the better to consider them individually, I should view them as subsisting between straight lines, than which I could find no objects more simple, or capable of being more distinctly represented to my imagination and senses, and on the other hand that, in order to retain them in the memory or embrace an aggregate of many, I should express them by certain characters, the briefest possible.” Such is the basis of the algebraical or modern analytical geometry. The problem of the curves is solved by their reduction to a problem of straight lines; and the locus of any point is determined by its distance from two given straight lines—the axes of co-ordinates. Thus Descartes gave to modern geometry that abstract and general character in which consists its superiority to the geometry of the ancients. In another question connected with this, the problem of drawing tangents to any curve, Descartes was drawn into a controversy with Fermat (1590–1663), Roberval (1602–1673), and Desargues (1593–1662). Fermat and Descartes agreed in regarding the tangent to a curve as a secant of that curve with the two points of intersection coinciding, while Roberval regarded it as the direction of the composite movement by which the curve can be described. Both these methods, differing from that now employed, are interesting as preliminary steps towards the method of fluxions and the differential calculus. In pure algebra Descartes expounded and illustrated the general methods of solving equations up to those of the fourth degree (and believed that his method could go beyond), stated the law which connects the positive and negative roots of an equation with the changes of sign in the consecutive terms, and introduced the method of indeterminate coefficients for the solution of equations.⁴ Attempts have been recklessly made to claim some of these innovations for the English algebraists Oughtred and Harriot, and others for the mathematicians of the Continent; but such assertions are based upon no proof, and, if true, would only illustrate the genius of the man who could pick out from other works all that was productive, and state it with a lucidity which makes it look his own discovery.

The *Geometry* of Descartes, unlike the other parts of his essays, is not easy reading. It dashes at once into the middle of the subject with the examination of a problem which had baffled the ancients, and seems as if it were tossed at the heads of the French geometers as a challenge. An edition of it appeared subsequently, with notes by his friend De Beaune, calculated to smooth the difficulties of the work. All along mathematics was regarded by Descartes rather as the envelope than the foundation of his method; and the “universal mathematical science” which he sought after was only the prelude of a universal science of all-embracing character.⁵

The method of Descartes rests upon the proposition that all the objects of our knowledge fall into series, of which the members are more or less known by means of one

¹ *Regulae*, Œuvr. xi. 202

⁴ *Geométrie*, book iii.

⁵ Œuvres, xi. 224

another. In every such series or group there is a dominant element, simple and irresolvable, the standard on which the rest of the series depends, and hence, so far as that group or series is concerned, absolute. The other members of the group are relative and dependent, and only to be understood as in various degrees subordinate to the primitive conception. The characteristic by which we recognize the fundamental element in a series is its intuitive or self-evident character, it is given by "the evident conception of a healthy and attentive mind so clear and distinct that no doubt is left."¹ Having discovered this prime or absolute member of the group, we proceed to consider the degrees in which the other members enter into relation with it. Here deduction comes into play to show the dependence of one term upon the others; and, in the case of a long chain of intervening links, the problem for intelligence is so to enunciate every element, and so to repeat the connection that we may finally grasp all the links of the chain in one. In this way we, as it were, bring the causal or primal term and its remotest dependent immediately together, and raise a derivative knowledge into one which is primary and intuitive. Such are the four points of Cartesian method:—(1) Truth requires a clear and distinct conception of its object, excluding all doubt, (2) the objects of knowledge naturally fall into series or groups; (3) in these groups investigation must begin with a simple and indecomposable element, and pass from it to the more complex and relative elements; (4) an exhaustive and immediate grasp of the relations and interconnection of these elements is necessary for knowledge in the fullest sense of that word.²

"There is no question," he says in anticipation of Locke and Kant, "more important to solve than that of knowing what human knowledge is and how far it extends." "This is a question which ought to be asked at least once in their lives by all who seriously wish to gain wisdom. The inquirer will find that the first thing to know is intellect, because on it depends the knowledge of all other things. Examining next what immediately follows the knowledge of pure intellect, he will pass in review all the other means of knowledge, and will find that they are two (or three), the imagination and the senses (and the memory). He will therefore devote all his care to examine and distinguish these three means of knowledge; and seeing that truth and error can, properly speaking, be only in the intellect, and that the two other modes of knowledge are only occasions, he will carefully avoid whatever can lead him astray."³ This separation of intellect from sense, imagination, and memory is the cardinal precept of the Cartesian logic, it marks off clear and distinct (i. e., adequate and vivid) from obscure, fragmentary, and incoherent conceptions.

The *Discourse of Method* and the *Meditations* apply what the *Rules for the Direction of the Mind* had regarded as particular instances to our conceptions of the world as a whole. They propose, that is, to find a simple and indecomposable point, or absolute element, which gives to the world and thought their order and systematization. The grandeur of this attempt is perhaps unequalled in the annals of philosophy. The three main steps in the argument are the veracity of our thought when that thought is true to itself, the inevitable uprising of thought from its fragmentary aspects in our habitual consciousness to the infinite and perfect existence which God is, and the ultimate reduction of the material universe to extension and local movement. These are the central dogmas of logic, metaphysics, and physics, from which start the subsequent inquiries of Locke, Leibnitz, and Newton. They are also

the direct antitheses to the scepticism of Montaigne and Pascal, to the materialism of Gassendi and Hobbes, and to the superstitious anthropomorphism which defaced the re-awakening sciences of nature. Descartes laid down the lines on which modern philosophy and science were to build. But himself no trained metaphysician, and unsusceptible to the lessons of history, he gives but fragments of a system which are held together, not by their intrinsic consistency, but by the vigour of his personal conviction transcending the weaknesses and collisions of his several arguments. "All my opinions," he says, "are so conjoined, and depend so closely upon one another, that it would be impossible to appropriate one without knowing them all."⁴ Yet every disciple of Cartesianism seems to disprove the dictum by his example.

The very moment when we begin to think, says Descartes, when we cease to be merely receptive, when we draw back and fix our attention on any point whatever of our belief,—that moment doubt begins. If we even stop for an instant to ask ourselves how a word ought to be spelled, the deeper we ponder that one word by itself the more hopeless grows the hesitation. The doubts thus awakened must not be stifled, but pressed systematically on to the point, if such a point there be, where doubt confutes itself. The doubt as to the details is natural; it is no less natural to have recourse to authority to silence the doubt. The remedy proposed by Descartes is (while not neglecting our duties to others, ourselves, and God) to let doubt range unchecked through the whole fabric of our customary convictions. One by one they refuse to render any reasonable account of themselves, each seems a mere chance, and the whole tends to elude us like a mirage which some malignant power creates for our illusion. Attacked in detail, they vanish one after another into as many teasing spectra of uncertainty. We are seeking from them what they cannot give. But when we have done our worst in unsettling them, we come to an ultimate point in the fact that it is we who are doubting, we who are thinking. We may doubt that we have hands or feet, that we sleep or wake, and that there is a world of material things around us; but we cannot doubt that we are doubting. We are certain that we are thinking, and in so far as we are thinking we are. *Je pense, donc je suis.* Of this we cannot doubt, and therefore this is true. In other words, the criterion of truth is a clear and distinct conception, excluding all possibility of doubt.

The fundamental point thus established is the veracity of consciousness when it does not go beyond itself, or does not postulate something which is external to itself. We are thinking; we are minds; and from the mere primary intuition, which results when we analyze our doubts, we cannot tell that we are more. At this point Gassendi arrested Descartes and addressed his objections to him as pure intelligence,—*O mens!* But even this *mens*, or mind, is but a point—we have found no guarantee as yet for its continuous existence. The analysis must be carried deeper if we are to gain any further conclusions.

Amongst the ideas or elements of our thought there are some which we can make and unmake at our pleasure, there are others which come and go without our wish, there is also a third class which is of the very essence of our thinking, and which dominates our conceptions. We find that all our ideas of limits, sorrows, and weaknesses presuppose an infinite, perfect, and ever-blessed something beyond them and including them,—that all our ideas, in all their series, converge to one central idea, in which they find their explanation. The formal fact of thinking is what constitutes our being; but this thought of which we

¹ Œuvres, xi. 212. ² Disc. de Méthode, part ii. ³ Œuvres, xi. 243.

⁴ Œuvres, vii. 381.

are certain leads us back, when we consider its concrete contents, to the necessary pre-supposition on which our ideas depend, the ultimate totality in which they are all reconciled, the permanent cause on which they and we as conscious beings depend. We have therefore, says Descartes, the idea of an infinite, perfect, and all powerful being which cannot be the creation of ourselves, and must be given by some being who really possesses all that we in idea attribute to him. Such a being he identifies with God. But the ordinary idea of God can scarcely be identified with such a conception. "The majority of men," he says himself, "do not think of God as an infinite and incomprehensible being, and as the sole author from whom all things depend; they go no further than the letters of his name."¹ "The vulgar almost imagine him as a finite thing." The God of Descartes is not merely the creator of the material universe; he is also the father of all truth in the intellectual world. "The metaphysical truths," he says, "styled eternal have been established by God, and, like the rest of his creatures, depend entirely upon him. To say that these truths are independent of him is to speak of God as a Jupiter or a Saturn,—to subject him to Styx and the Fates."² The laws of thought, the truths of number, are the decrees of God. The expression is anthropomorphic, no less than the dogma of material creation; but it is an attempt to affirm the unity of the intellectual and the material world. Descartes establishes a philosophic monotheism,—by which the medieval polytheism of substantial forms, essences, and eternal truths fades away before God, who is the ruler of the intellectual world no less than of the kingdom of nature and of grace.

To attach a clear and definite meaning to the Cartesian doctrine of God, to show how much of it comes from the Christian theology and how much from the logic of idealism, how far the conception of a personal being as creator and preserver mingles with the pantheistic conception of an infinite and perfect something which is all in all, would be to go beyond Descartes and to ask for a solution of difficulties of which he was scarcely aware. It seems impossible to deny that the tendency of his principles and his arguments is mainly in the line of a metaphysical absolute, as the necessary completion and foundation of all being and knowledge. Through the truthfulness of that God as the author of all truth he derives a guarantee for our perceptions in so far as these are clear and distinct. And it is in guaranteeing the veracity of our clear and distinct conceptions that the value of his deduction of God seems in his own estimate to rest. All conceptions which do not possess these two attributes—of being vivid in themselves and discriminated from all others—cannot be true. But the larger part of our conceptions are in such a predicament. We think of things not in the abstract elements of the things themselves, but in connection with, and in language which presupposes, other things. Our idea of body, e.g., involves colour and weight, and yet when we try to think carefully, and without assuming anything, we find that we cannot attach any distinct idea to these terms when applied to body. In truth therefore these attributes do not belong to body at all; and if we go on in the same way testing the received qualities of matter, we shall find that in the last resort we understand nothing by it but extension, with the secondary and derivative characters of divisibility and mobility.

But it would again be useless to ask how extension as the characteristic attribute of matter is related to mind which thinks, and how God is to be regarded in reference to extension. The force of the universe is swept up and gathered in God, who communicates motion to the parts of

extension, and sustains that motion from moment to moment; and in the same way the force of mind has really been concentrated in God. Every moment one expects to find Descartes saying with Hobbes that man's thought has created God, or with Spinoza and Malebranche that it is God who really thinks in the apparent thought of man. After all, the metaphysical theology of Descartes, however essential in his own eyes, serves chiefly as the ground for constructing his theory of man and of the universe. His fundamental hypothesis relegates to God all forces in their ultimate origin. Hence the world is left open for the free play of mechanics and geometry. The disturbing conditions of will, life, and organic forces are eliminated from the problem; he starts with the clear and distinct idea of extension, figured and moved, and thence by mathematical laws he gives a hypothetical explanation of all things. Such explanation of physical phenomena is the main problem of Descartes, and it goes on encroaching upon territories once supposed proper to the mind. Descartes began with the certainty that we are thinking beings, that region remains untouched; but up to its very borders the mechanical explanation of nature reigns unchecked.

The physical theory, in its earlier form in the *World*, and in its later in the *Principles of Philosophy* (which the present account follows), rests upon the metaphysical conclusions of the *Meditations*. It proposes to set forth the genesis of the existing universe from principles which can be plainly understood, and according to the acknowledged laws of the transmission of movement. The idea of force is one of those obscure conceptions which originate in an obscure region, in the sense of muscular power. The true physical conception is motion, the ultimate ground of which is to be sought in God's infinite power. Accordingly the quantity of movement in the universe, like its mover, can neither increase nor diminish. The only circumstance which physics has to consider is the transference of movement from one particle to another, and the change of its direction. Man himself cannot increase the sum of motion; he can only alter its direction. The whole conception of force may disappear from a theory of the universe, and we can adopt a geometrical definition of motion as the shifting of one body from the neighbourhood of those bodies which immediately touch it, and which are assumed to be at rest, to the neighbourhood of other bodies. Motion, in short, is strictly locomotion, and nothing else.

Descartes has laid down three laws of nature, and seven secondary laws regarding impact. The latter are to a large extent incorrect. The first law affirms that every body, so far as it is altogether unaffected by extraneous causes, always perseveres in the same state of motion or of rest; and the second law that simple or elementary motion is always in a straight line.³ These doctrines of inertia, and of the composite character of curvilinear motion, were scarcely apprehended even by Kepler or Galileo, but they follow naturally from the geometrical analysis of Descartes.

Extended body has no limits to its extent, though the power of God has divided it in lines discriminating its parts in endless ways. The infinite universe is infinitely full of matter. Empty space, as distinguished from material extension, is a fictitious abstraction. There is no such thing really as a vacuum, any more than there are atoms or ultimate indivisible particles. In both these doctrines of a priori science Descartes has not been subverted, but, if anything, corroborated by the results of experimental physics, for the so-called atoms of chemical theory already presuppose, from the Cartesian point of view, certain aggregations of the primitive particles of matter. Descartes regards matter as uniform in character

¹ Œuvres, vi. 132.

² Œuvres, vi. 109.

³ Princip., pt. ii. 37

throughout the universe; he anticipates, as it were, from his own transcendental ground, the revolutions of spectrum analysis as applied to the sun and stars. We have then to think of a full universe of matter (and matter = extension) divided and figured with endless variety, and set (and kept) in motion by God, and any sort of division, figure, and motion will serve the purposes of our supposition as well as another. "Scarcely any supposition,"¹ he says, in ominous language, "can be made from which the same result, though possibly with greater difficulty, might not be deduced by the same laws of nature; for since, in virtue of these laws, matter successively assumes all the forms of which it is capable, if we consider these forms in order, we shall at one point or other reach the existing form of the world, so that no error need here be feared from a false supposition." As the movement of one particle in a closely-packed universe is only possible if all other parts move simultaneously, so that the last in the series steps into the place of the first; and as the figure and division of the particles varies in each point in the universe, there will inevitably at the same instant result throughout the universe an innumerable host of more or less circular movements, and of vortices or whirlpools of material particles, varying in size and velocity. Taking for convenience a limited portion of the universe, we observe that in consequence of the circular movement the particles of matter have their corners pared off by rubbing against each other; and two species of matter thus arise,—one consisting of small globules which continue their circular motion with a (centrifugal) tendency to fly off from the centre as they swing round the axis of rotation, while the other, consisting of the fine dust—the filings and parings of the original particles—gradually becoming finer and finer, and losing its velocity, tends (centripetally) to accumulate in the centre of the vortex, which has been gradually left free by the receding particles of globular matter. This finer matter which collects in the centre of each vortex is the *first* matter of Descartes—it constitutes the sun or star. The spherical particles are the *second* matter of Descartes, and their tendency to propel one another from the centre in straight lines towards the circumference of each vortex is what gives rise to the phenomenon of light radiating from the central star. This second matter is atmosphere or firmament, which envelops and revolves around the central accumulation of first matter.

A third form of matter is produced from the original particles. As the small filings produced by friction seek to pass through the interstices between the rapidly revolving spherical particles in the vortex, they are detained and become twisted and channelled in their passage, and when they reach the edge of the inner ocean of solar dust they settle upon it as the froth and foam produced by the agitation of water gathers upon its surface. These form what we term spots in the sun. In some cases they come and go, or dissolve into an other round the sun; but in other cases they gradually increase until they form a dense crust round the central nucleus. In course of time the star, with its expansive force diminished, suffers encroachments from the neighbouring vortices, and at length they catch it up. If the velocity of the decaying star be greater than that of any part of the vortex which has swept it up, it will ere long pass out of the range of that vortex, and continue its movement from one to another. Such a star is a comet. But in other cases the encrusted star settles in that portion of the revolving vortex which has a velocity equivalent to its own, and so continues to revolve in the vortex, wrapt in its own firmament. Such a reduced and

unpoorished star is a planet; and the several planets of our solar system are the several vortices which from time to time have been swept up by the central sun-vortex. The same considerations serve to explain the moon and other satellites. They, too, were once vortices, swallowed up by some other, which at a later day fell a victim to the sweep of our sun.

Such in mere outline is the celebrated theory of vortices, which for about 20 years after its promulgation reigned supreme in science, and for much longer time opposed a tenacious resistance to rival doctrines. It is one of the grandest hypotheses which ever have been formed to account by mechanical processes for the movements of the universe. While chemistry rests in the acceptance of ultimate heterogeneous elements, the vortex-theory assumed uniform matter through the universe, and reduced cosmical physics to the same principles as regulate terrestrial phenomena. It ended the old Aristotelian distinction between the sphere beneath the moon and the starry spaces beyond. It banished the spirits and geni, to which even Kepler had assigned the guardianship of the planetary movements; and, if it supposes the globular particles of the envelope to be the active force in carrying the earth round the sun, we may remember that Newton himself assumed an ether for somewhat similar purposes. The great argument on which the Cartesians founded their opposition to the Newtonian doctrines was that attraction was an occult quality, not wholly intelligible by the aid of mere mechanics. The Newtonian theory is an analysis of the elementary movements which in their combination determine the planetary orbits, and gives the formula of the proportions according to which they act. But the Cartesian theory, like the later speculations of Kant and Laplace, proposes to give a hypothetical explanation of the circumstances and motions which in the normal course of things led to the state of things required by the law of attraction. In the judgment of D'Alembert the Cartesian theory was the best that the observations of the age admitted, and "its explanation of gravity was one of the most ingenious hypotheses which philosophy ever imagined." That the explanation fails in detail is undoubted: it does not account for the ellipticity of the planets; it would place the sun, not in one focus, but in the centre of the ellipse; and it would make gravity directed towards the centre only under the equator. But these defects need not blind us to the fact that this hypothesis made the mathematical progress of Hooke, Borelli, and Newton much more easy and certain. Descartes professedly assumed a simplicity in the phenomena which they did not present. But such a hypothetical simplicity is the necessary step for solving the more complex problems of nature. The danger lies not in forming such hypotheses, but in regarding them as final, or as more than an attempt to throw light upon our observation of the phenomena. In doing what he did, Descartes actually exemplified that reduction of the processes of nature to mere transposition of the particles of matter, which in different ways was a leading idea in the minds of Bacon, Hobbes, and Gassendi. The defects of Descartes lie rather in his apparently imperfect apprehension of the principle of movements uniformly accelerated which his contemporary Galileo had illustrated and insisted upon, and in the indistinctness which attaches to his views of the transmission of motion in cases of impact. In modern times, it may be added, a theory of vortex-atoms has been suggested to explain the constitution of matter. But except in name it has but slight analogy with Cartesian doctrine, and finds a parallel, if anywhere, in a modification of that doctrine by Malebranche.

Besides the last two parts of the *Principles of Philosophy*, the physical writings of Descartes include the *Dioptrics*

¹ Princip, pt. iii. 47.

and *Meteors*, as well as passages in the letters. His optical investigations are perhaps the subject in which he most contributed to the progress of science; and the lucidity of exposition which marks his *Dioptrics* stands conspicuous even amid the generally luminous style of his works. Its object is a practical one, to determine by scientific considerations the shape of lens best adapted to improve the capabilities of the telescope, which had been invented not long before. The conclusions at which he arrives have not been so useful as he imagined, in consequence of the mechanical difficulties. But the investigation by which he reaches them has the merit of first prominently publishing and establishing the law of the refraction of light. Attempts have been made, principally founded on some jealous remarks of Huyghens, to show that Descartes had learned the principles of refraction from the manuscript of a treatise by Willebrord Snell, but facts do not bear out the charge; and, so far as Descartes founds his optics on any one, it is on the researches of Kepler. In any case the glory of the discovery is to a large extent his own, for his proof of the law is founded upon the theory that light is the tendency or inclination of the subtle particles of ethereal matter to propagate their movement in straight lines from the sun or luminous body to the eye. And thus he approximates to the wave theory of light, though he supposed, like his contemporaries, that the transmission of light was instantaneous. The chief of his other contributions to optics was the explanation of the rainbow—an explanation far from complete, since the unequal refrangibility of the rays of light was yet undiscovered—but a decided advance upon his predecessors, notably on the *De radiis visus et lucis* (1611) of Marc-Antonio de Dominis, archbishop of Spalato, from whom careless critics have assumed that he derived his ideas.

If Descartes had contented himself with thus explaining the phenomena of gravity, heat, magnetism, light, and similar forces by means of the molecular movements of his vortices, even such a theory would have excited admiration by its daring grandeur. But Descartes did not stop short in the region of what is usually termed physics. Chemistry and biology are alike swallowed up in the one science of physics, and reduced to a problem of mechanism. This theory, he believed, would afford an explanation of every phenomenon whatever, and in nearly every department of knowledge he has given specimens of its power. But the most remarkable and daring application of the theory was to account for the phenomena of organic life, especially in animals and man. "If we possessed a thorough knowledge," he says,¹ "of all the parts of the seed of any species of animal (*e.g.*, man), we could from that alone, by reasons entirely mathematical and certain, deduce the whole figure and conformation of each of its members, and, conversely, if we knew several peculiarities of this conformation, we could from these deduce the nature of its seed." The organism in this way is regarded as a machine, constructed from the particles of the seed, which in virtue of the laws of motion have arranged themselves (always under the governing power of God) in the particular animal shape in which we see them. The doctrine of the circulation of the blood, which Descartes adopted from Harvey, supplied additional arguments in favour of his mechanical theory, and he probably did much to popularize the discovery. A fire without light, compared to the heat which gathers in a haystack when the hay has been stored before it was properly dry—heat, in short, as an agitation of the particles—is the motive cause of the contraction and dilatations of the heart. Those finer particles of the blood which become extremely rarefied during this process

pass off in two directions—one portion, and the least important in the theory, to the organs of generation, the other portion to the cavities of the brain. There not merely do they serve to nourish the organ, they also give rise to a fine ethereal flame or wind through the action of the brain upon them, and thus form the so-called "animal" spirits. From the brain these spirits are conveyed through the body by means of the nerves, regarded by Descartes as tubular vessels, resembling the pipes conveying the water of a spring to act upon the mechanical appliances in an artificial fountain. The nerves conduct the animal spirits to act upon the muscles, and in their turn convey the impressions of the organs to the brain.

Man and the animals as thus described are compared to automata, and termed machines. The vegetative and sensitive souls which the Aristotelians had introduced to break the leap between inanimate matter and man are ruthlessly swept away; only one soul, the rational, remains, and that is restricted to man. One hypothesis supplants the various principles of life: the rule of absolute mechanism is as complete in the animal as in the cosmos. Reason and thought, the essential quality of the soul, do not belong to the brutes; there is an impassable gulf fixed between man and the lower animals. The only sure sign of reason is the power of language—*i.e.*, of giving expression to general ideas; and language in that sense is not found save in man. The cries of animals are but the working of the curiously-contrived machine, in which, when one portion is touched in a certain way, the wheels and springs concealed in the interior perform their work, and, it may be, a note supposed to express joy or pain is evolved; but there is no consciousness or feeling. "The animals act naturally and by springs, like a watch."² "The greatest of all the prejudices we have retained from our infancy is that of believing that the beasts think."³ If the beasts can properly be said to see at all, "they see as we do when our mind is distracted and keenly applied elsewhere; the images of outward objects paint themselves on the retina, and possibly even the impressions made in the optic nerves determine our limbs to different movements, but we feel nothing of it all, and move as if we were automata."⁴ I will not believe, said the Cartesian Chancelier, that a beast thinks until the beast tells me so itself. The sentence of the animal to the lash of his tyrant is not other than the sensitivity of the plant to the influences of light and heat. It is not much comfort to learn further from Descartes that "he denies life to no animal, but makes it consist in the mere heat of the heart. Nor does he deny them feeling in so far as it depends on the bodily organs."⁵

Descartes, with an unusual fondness for the letter of Scripture, quotes oftener than once in support of this monstrous doctrine the dictum that "The blood is the life;" and he remarks, with some sarcasm possibly, that it is a comfortable theory for the eaters of animal flesh. And the doctrine found acceptance among some whom it enabled to get rid of the difficulties raised by Montaigne and those who allowed more difference between animal and animal than between the higher animals and man. It also encouraged vivisection—a practice common with Descartes himself.⁶ The recluses of Port Royal seized it eagerly, discussed automatism, dissected living animals in order to show to a morbid curiosity the circulation of the blood, were careless of the cries of tortured dogs, and finally embalmed the doctrine in a syllogism of their logic,—No matter thinks; every soul of beast is matter: therefore no soul of beast thinks.

But whilst all the organic processes in man go on

mechanically, and though by reflex action he may repel attack unconsciously, still the first affirmation of the system was that man was essentially a thinking being; and, while we retain this original dictum, it must not be supposed that the mind is a mere spectator, or like the boatman in the boat. Of course a unity of nature is impossible between mind and body so described. And yet there is a unity of composition, a unity so close that the compound is "really one and in a sense indivisible." You cannot in the actual man cut soul and body asunder; they interpenetrate in every member. But there is one point in the human frame—a point midway in the brain, single and free, which may in a special sense be called the seat of the mind. This is the so-called conarium, or pineal gland, where in a minimized point the mind on one hand and the vital spirits on the other meet and communicate. In that gland the mystery of creation is concentrated; thought meets extension and directs it; extension moves towards thought and is perceived. Two clear and distinct ideas, it seems, produce an absolute mystery. Mind, driven from the field of extension, erects its last fortress in the pineal gland. In such a state of despair and destitution there is no hope for spiritualism, save in God; and Clauberg, Geulinx, and Malebranche all take refuge under the shadow of His wings to escape the tyranny of extended matter.

In the psychology of Descartes there are two fundamental modes of thought,—perception and volition. "It seems to me," he says, "that in receiving such and such an idea the mind is passive, and that it is active only in volition, that its ideas are put in it partly by the objects which touch the senses, partly by the impressions in the brain, and partly also by the dispositions which have preceded in the mind itself and by the movements of its will."¹ The will, therefore, as being more originaive, has more to do with true or false judgments than the understanding. Unfortunately, Descartes is too lordly a philosopher to explain distinctly what either understanding or will may mean. But we gather that in two directions our reason is bound up with bodily conditions, which make or mar it, according as the will, or central energy of thought, is true to itself or not. In the range of perception, intellect is subjected to the material conditions of sense, memory, and imagination; and in infancy, when the will has allowed itself to assent precipitately to the conjunctions presented to it by these material processes, thought has become filled with obscure ideas. In the moral sphere the passions or emotions (which Descartes reduces to the six primitive forms of admiration, love, hatred, desire, joy, and sadness) are the perceptions or sentiments of the mind, caused and maintained by some movement of the vital spirits, but specially referring to the mind only. The presentation of some object of dread, for example, to the eye has or may have a double effect. On one hand the animal spirits "reflected"² from the image formed on the pineal gland proceed through the nervous tubes to make the muscles turn the back and lift the feet, so as to escape the cause of the terror. Such is the reflex and mechanical movement independent of the mind. But, on the other hand, the vital spirits cause a movement in the gland by which the mind perceives the affection of the organs, learns that something is to be loved or hated, admired or shunned. Such perceptions dispose the mind to pursue what nature dictates as useful. But the estimate of goods and evils which they give is indistinct and unsatisfactory. The office of reason is to give a true and distinct appreciation of the values of goods and evils; or firm and determinate judgments touching the knowledge of good and evil are our proper arms against the influence of the passions.³ We are free, therefore, through knowledge: ex

magna luce in intellectu sequitur magna propensio in voluntate, et omnis peccans est ignorans. "If we clearly see that what we are doing is wrong, it would be impossible for us to sin, so long as we saw it in that light."⁴ Thus the highest liberty, as distinguished from mere indifference, proceeds from clear and distinct knowledge, and such knowledge can only be attained by firmness and resolution, the continued exercise of the will. Thus in the i.e., by the nature of God, will and intellect perfection of man, as in the nature of God, will and intellect must be united. For thought will is as necessary as understanding. And innate ideas therefore are mere capacities or tendencies,—possibilities which apart from the will to think may be regarded as nothing at all.

The philosophy of Descartes fought its first battles and gained its first triumphs in the country of his adoption. In his lifetime his views had been taught in Utrecht and Leyden. In the universities of the Netherlands and of Lower Germany, as yet free from the conservatism of the old-established seats of learning, the new system gained an easy victory over Aristotelianism, and, as it was adapted for lectures and examinations, soon became almost as scholastic as the doctrines it had supplanted. At Leyden, taught by De Raey, Heerebord, Heidan, and Volder; at Utrecht, by De Bruyn and P. Burmann, and Lambert Welthuysen (the last a private student); at Groningen, by Maresius, Gousset, and Tobias André; at Franeker, by Ruarius Andala, at Breda, Nimeguen, Harderwyk, Duisburg, and Herborn, and at the Catholic university of Louvain, Cartesianism was warmly expounded and defended in seats of learning, of which many are now left desolate, and by adherents whose lucubrations have for the most part long lost interest for any but the antiquary.

The Cartesianism of Holland was a child of the universities, and its literature is mainly composed of commentaries upon the original texts, of theses discussed in the schools, and of systematic expositions of Cartesian philosophy for the benefit of the student. Three names stand out in this Cartesian professoriate,—Wittich, Clauberg, and Geulinx. Wittich (1625–1685), professor at Duisburg and Leyden, is a representative of the moderate followers, who professed to reconcile the doctrines of their school with the faith of Christendom, and to refute the theology of Spinoza. Clauberg (like Wittich, a German), professor of philosophy at Herborn and Duisburg, died while still young in 1665. Like a schoolman on Aristotle, he has, clause by clause, commented upon the *Meditations* of Descartes; but he specially claims notice for his work *De corporis et animæ in homine conjunctio*, where he maintains that the bodily movements are merely procaccetic causes (i.e., antecedents, but not strictly causes) of the mental action, and sacrifices the independence of man to the omnipotence of God. The same tendency to absorb all particular causes and movements in God is still more pronounced in Geulinx (1625–1669), who for the last six years of his life taught privately at Leyden. With Geulinx the reciprocal action of mind and body is altogether denied; they resemble two clocks, so made by the artificer as to strike the same hour together. The mind can only act upon itself; beyond that limit, the power of God must intervene to make any seeming interaction possible between body and soul. Such are the half-hearted attempts at consistency in Cartesian thought, which eventually culminate in the pantheism of Spinoza.

Descartes occasionally had not scrupled to interpret the Scriptures according to his own tenets, while still maintaining, when their letter contradicted him, that the Bible was not meant to teach the sciences. Similar tendencies are found amongst his followers. Whilst Protestant

⁴ Œuvres, ix. 170.

opponents put him in the list of atheists like Vanini, and the Catholics held him as dangerous as Luther or Calvin, there were zealous adherents who ventured to prove the theory of vortices in harmony with the book of Genesis. It was this rationalistic treatment of the sacred writings which helped to confound the Cartesians with the allegorical school of John Cusceius, as their liberal doctrines in theology justified the vulgar identification of them with the heresies of Socinian and Arminian. The chief names in this advanced theology connected with Cartesian doctrines are Meyer, the friend and editor of Spinoza, author of a work termed *Philosophia Scripturæ Interpres* (1666); Balthasar Bekker, whose *World Bewitched* helped to discredit the superstitions fancies about the devil, and Spinoza, whose *Tractatus Theologico-Politicus* is in some respects the classical type of rational criticism up to the present day. Against this work and the *Ethics* of Spinoza the orthodox Cartesians (who were in the majority), no less than sceptical hangers-on like Bayle, raised an all but universal howl of reprobation, scarcely broken for about a century.

In France Cartesianism won society and literature before it penetrated into the universities. Clerselier (the friend of Descartes and his literary executor), his son-in-law Rohault (who achieved that relationship through his Cartesianism), and others, opened their houses for readings to which the intellectual world of Paris—its learned professors not more than the courtiers and the fair sex,—flocked to hear the new doctrines explained, and possibly discuss their value. Grand seigneurs, like the prince of Condé, the Duc de Nevers, and the Marquis de Vardes, were glad to vary the monotony of their feudal castles by listening to the eloquent rehearsals of Malebranche or Regis. And the salons of Madame de Sevigné, of her daughter Mina, de Grignan, and of the Duchesse de Maine for a while gave the questions of philosophy a place among the topics of polite society, and furnished to Molière the occasion of his *Femmes Savantes*. The château of the Duc de Luynes, the translator of the *Meditations*, was the home of a Cartesian club, that discussed the questions of automatism and of the composition of the sun from filings and parings, and rivalled Port Royal in its vivisections. The Cardinal de Retz in his leisurely age at Commercy found amusement in presiding at disputations between the more moderate Cartesians and Don Robert Desgabets, who interpreted Descartes in an original way of his own. Though rejected by the Jesuits, who found peripatetic formulæ a faithful weapon against the enemies of the church, Cartesianism was warmly adopted by the Oratory, which saw in Descartes something of St Augustine, by Port Royal, which discovered a connection between the new system and Jansenism, and by some amongst the Benedictines and the order of Ste Geneviève.

The popularity which Cartesianism thus gained in the social and literary circles of the capital was largely increased by the labours of Pierre-Sylvain Regis (1632–1707). On his visit to Toulouse in 1665, with a mission from the Cartesian chiefs, his lectures excited boundless interest; ladies threw themselves with zeal and ability into the study of philosophy; and Regis himself, like a public benefactor in some old Greek town, was made the guest of the civic corporation. In 1671 scarcely less enthusiasm was aroused in Montpellier; and in 1680 he opened a course of lectures at Paris, with such acceptance that intending hearers had to secure their seats some time before the lecture began. Regis, by removing the paradoxes and adjusting the metaphysics to the popular powers of apprehension, made Cartesianism popular, and reduced it to a regular system.

But a check was at hand. Descartes, in his correspondence with the Jesuits, had shown an almost cringing eagerness to have their powerful organization on his side.

Especially he had written to Père Mesland, one of the order, to show how the Catholic doctrine of the eucharist might be made compatible with his theories of matter. But his undue haste to arrange matters with the church only served to compromise him more deeply. Unwise admirers and malicious opponents exaggerated the theological bearings of his system in this detail; and the efforts of the Jesuits succeeded in getting the works of Descartes, in November 1663, placed upon the Index of prohibited books,—*donec corrigantur*. Thereupon the power of church and state enforced by positive enactments the passive resistance of old institutions to the novel theories. In 1667, the oration at the interment was forbidden by royal order. In 1669, when the chair of philosophy at the Collège Royal fell vacant, one of the four selected candidates had to sustain a thesis against “the pretended new philosophy of Descartes.” In 1671 the archbishop of Paris, by the king's order, summoned the heads of the university to his presence, and enjoined them to take stricter measures against philosophical novelties dangerous to the faith. In 1673 a decree of the Parliament against Cartesian and other unlicensed theories was on the point of being issued, and was only checked in time by the appearance of a burlesque mandamus against the intruder Reason, composed by Boileau and some of his brother-poets. Yet in 1675 the university of Angers was empowered to repress all Cartesian teaching within its domain, and actually appointed a commission charged to look for such heresies in the theses and the students' note-books of the college of Anjou belonging to the Oratory. In 1677 the university of Caen adopted not less stringent measures against Cartesianism. And so great was the influence of the Jesuits, that the congregation of St Maur, the canons of Ste Geneviève, and the Oratory laid their official ban on the obnoxious doctrines. From the real or fancied *rapprochements* between Cartesianism and Jansenism, it became for a while impolitic, if not dangerous, to avow too loudly a preference for Cartesian theories. Regis was constrained to hold back for ten years his *System of Philosophy*; and when it did appear, in 1690, the name of Descartes was absent from the title-page. There were other obstacles besides the mild persecutions of the church. Pascal and other members of Port Royal openly expressed their doubts about the place allowed to God in the system; the adherents of Gassendi met it by resuscitating atoms; and the Aristotelians maintained their substantial forms as of old; the Jesuits argued against the arguments for the being of God, and against the theory of innate ideas; whilst Huet, bishop of Avranches, once a Cartesian himself, made a vigorous onslaught on the contempt in which his former comrades held literature and history, and enlarged on the vanity of all human aspirations after rational truth.

The greatest and most original of the French Cartesians was Malebranche. His *Recherche de la Vérité*, in 1674, was the baptism of the system into a theistic religion which borrowed its imagery from Augustine; it brought into prominence the metaphysical base which De la Forge, Rohault, and Regis had neither cared for nor understood. But this doctrine was a criticism and a divergence, no less than a consequence, from the principles in Descartes; and it brought upon Malebranche the opposition, not merely of the Cartesian physicists, but also of Arnauld, Fencelon, and Bossuet, who found, or hoped to find, in the *Meditations*, as properly understood, an ally for theology. Popular enthusiasm, however, was with Malebranche, as twenty years before it had been with Descartes, he was the fashion of the day; and his disciples rapidly increased both in France and abroad.

In 1705 Cartesianism was still subject to prohibitions from the authorities; but in a project of new statutes,

drawn up for the faculty of arts at Paris in 1720, the *Method* and *Meditations* of Descartes were placed beside the *Organon* and the *Metaphysics* of Aristotle as text-books for philosophical study. And before 1725, readings, both public and private, were given from Cartesian texts in some of the Parisian colleges. But when this happened, Cartesianism was no longer either interesting or dangerous; its theories, taught as ascertained and verified truths, were as worthless as the systematic verbiage which preceded them. Already antiquated, it could not resist the wit and raillery with which Voltaire, in his *Lettres sur les Anglais* (1728), brought against it the principles and results of Locke and Newton. The old Cartesians, Mairan and especially Fontenelle, with his *Théorie des Tourbillons* (1752), struggled in vain to refute Newton by styling attraction an occult quality. Fortunately, the Cartesian method had already done its service, even where the theories were rejected. The Port Royalists, Nicole and Arnauld, had applied it to grammar and logic; Domat and Daguesseau to jurisprudence; Fontenelle, Perrault, and Terrasson to literary criticism, and a worthier estimate of modern literature. Though it never ceased to influence individual thinkers, it had handed on to Condillac its popularity with the masses. A Latin abridgment of philosophy, dated 1781, tells us that the innate ideas of Descartes are founded on no arguments, and are now universally abandoned. The ghost of innate ideas seems to be all that it had left.

In Germany a few Cartesian lecturers left their names at Leipsic and Halle, but the system took no root, any more than in Switzerland, where it had a brief reign at Geneva after 1669. In Italy the effects were more permanent. What is termed the *auto-mechanical* school of medicine, with Borelli (1608–1679) as its most notable name, entered in a way on the mechanical study of anatomy suggested by Descartes, but was probably much more dependent upon the positive researches of Galileo. At Naples there grew up a Cartesian school, of which the best known members are Michel Angelo Fardella (1650–1708) and Cardinal Gerbil (1718–1802), both of whom, however, attached themselves to the characteristic views of Malebranche.

In England Cartesianism took but slight hold. Henry More, who had given it a modified sympathy in the lifetime of the author, became its opponent in later years; and Cudworth differed from it in most essential points. Antony Legrand, from Douay, attempted to introduce it into Oxford, but failed. He is the author of several works, amongst others a system of Cartesian philosophy, where a chapter on "Angels" revives the methods of the schoolmen. His chief opponent was Samuel Parker, bishop of Oxford, who, in his attack on the irreligious novelties of the Cartesian treats Descartes (such is the irony of history) as a fellow criminal in infidelity with Hobbes and Gassendi. Rohault's version of the Cartesian physics was translated into English; and Malebranche found an ardent follower in John Norris (1667–1711). Of Cartesianism towards the close of the 17th century the only remnants were an overgrown theory of vortices, which received its death-blow from Newton, and a dubious phraseology about innate ideas, which found a witty executioner in Locke.

For an account of the metaphysical doctrines of Descartes, in their connections with Malebranche and Spinoza, see the article **CARTESIANISM**.

The chief editions of the collected works of Descartes are the two Latin texts in 8 vols. 4to by Elzevir 1713, and in 7 vols. 4to, Frankfurt, 1697, and the French edition by Cousin in 11 vols. 8vo, Paris, 1824–26. These include his so-called posthumous works, *The Rules for the Direction of the Mind*, *The Search for Truth by the Sight of Nature*, and other unimportant fragments, published (in Latin) in 1701. In 1859–60 Foucher de Careil published in two parts some unedited writings of Descartes from copies taken by Leibnitz from the original

papers. An edition of the philosophical works in 4 vols. 8vo, edited by Garnier, appeared at Paris, 1835. There is a good English translation of the *Method*, *Meditations*, and a small part of the *Principles*, first published at Edinburgh, 1858.

For the life of Descartes the chief authority is Baillet, *Vie de Descartes*, in 2 vols. 4to, 1691; of which a small abridgment, afterwards translated into English, appeared in 1692. There is a summary of it in Garnier's edition, and in Kuno Fischer's *Geschichte der Neuern Philosophie*, Band i. Th. 1, 8vo, Mannheim, 1866. See the *Éloge* of Thomas in Cousin's edition.

For the philosophy of Descartes, see besides the works referred to under **CARTESIANISM**, Bordes-Demoulin, *Le Cartésianisme*, 2d ed. Par. 1874; Damiron, *Histoire de la Philosophie du XVII. Siècle*; Renouvier, *Manuel de Philosophie Moderne*, Paris, 1842; Cousin, *Fragments Philosophiques*, vol. ii, Paris, 1838, *Fragments de Philosophie Cartésienne*, Paris, 1845, and in the *Journal des Savants*, 1860–61. A good estimate of the physical and mathematical labours is given in Ersch and Gruber's *Encyclopädie*, and Professor Huxley has lately, in the *Fortnightly Review*, vol. xvi, called attention to automatism. There are also several German works treating of his theology and metaphysics. (W. W.)

DESCHAMPS, EUSTACHE, called MOREL, a distinguished mediæval poet of France, was born at Vertus, in Champagne, early in the 14th century. The date of his birth has been approximately given as 1328, 1340, and 1345, according to the interpretation put upon certain vague statements of his own. It is certain that he lived under four kings—Philip VI., John, Charles V., and Charles VI. He studied the seven liberal arts at the university of Orleans. Early in life he proceeded to the court of France, and, after first entering the service of a prelate whose name he has not recorded, for more than thirty years took an active and prominent part in the joyous society of the day. Charged with a succession of honourable offices, he served nearly all the princes his contemporaries. His life was a long and romantic series of tournaments, feasts, and battles, and he was one of the most popular persons of his time. But before settling down to this life, he had a stormy youth of vicissitude. He was an eye-witness of the English invasion in 1358; he was in the siege of Rheims, and witnessed the march on Chartres; he was present also at the signing of the treaty at Bretigny. In 1360, as Châtelain of Vertus, he became the vassal of the young princess Isabella, to whom he paid great poetic homage. But he was then already a travelled man; he had visited Italy, Germany, and Hungary. Later on he took a part in the Flemish wars, and it was on this occasion that, about 1385, he received the surname, or nickname, of Morel, which he sometimes himself adopted in later life. He is believed, but not on very strong evidence, to have travelled in Syria and Egypt, and to have been captured and imprisoned by the Saracens. In France he lived the true life of a *trouvère*, wandering from castle to castle with his poems. He had a violent hatred for the English nation, fostered no doubt by the experiences of his youth; and this he has expressed very abundantly in his writings, particularly in the famous prophecy that England would be destroyed so thoroughly that no one should be able to point to her ruins. He was *huissier d'armes* to King Charles V., and by him appointed bailiff of Senlis and governor of Fismes. It was with great reluctance that, when he felt himself growing old, he retired from public life and went into a modest seclusion, where he occupied himself in the composition of a splanotic satire against women, entitled *Le Miroir de Mariage*; though 12,500 lines of this exist, he left it unfinished at his death, which took place about 1420. Eustache Deschamps was an accomplished courtier, but he was extremely ugly, he disarms criticism by calling himself "*Le Roi de Laidure*." His poems remained unprinted until our day, the great fault of them being a manuscript in the Royal Library at Paris, containing 1175 ballads, 171 rondeaux, 80 virelays, 14 lays, 28 farces, and various epistles and satires. This bulk of MSS. was edited and published in 4to by M. G. A.

Crapelet in 1832, preceded by a literary and historical monograph. The value of his writings being recognized, another and more critical edition was brought out, in 1849, by M. Prosper Tarbé. The same editor published *Le Miroir de Mariage* in 1865, and a long poem entitled *Le Lay des douze Etats du Monde*, in 1870. Deschamps excelled in the use of the ballad and chanson royal. In each of these forms of verse he was the greatest master of his time. One of his ballads is addressed to the English poet "Geoffroy Chaucier," to whom he says—

Tu es d'amours mondains dieux en Albie
Et de la Rose en la terre Angélique

In Eustache Deschamps the modern language of France first found a pure lyrical expression; his long life seems to connect the literature of Theobald IV. with that of Charles of Orleans.

DESERT. See PHYSICAL GEOGRAPHY.

DESFONTAINES, RENÉ LOUCHE (1751–1833), French botanist, was a native of Brittany, born at Tremblay, in the department of Ile-et-Vilaine, in 1751 or 1752. He was sent to the town school, but made slow progress in learning, and was at length dismissed by the schoolmaster as a dullard and a robber of apple orchards. This treatment left a life-long painful impression on his mind. At the college of Rennes, to which he was next sent, he applied himself heartily to study, and rejoiced in a success which falsified the judgment of his old master. From Rennes he passed to Paris, to study medicine; but this soon became a secondary pursuit, his chief attention being drawn to the study of plants. At Paris he acquired the friendship of Lemonnier, physician to the king, and of Jussieu. At the age of thirty he took his degree of M.D., and in 1783 he was elected member of the Academy of Sciences. In the same year he set out for North Africa, and spent two years in a scientific exploration of Barbary. In 1785 he returned to Paris, bringing with him a large collection of plants, animals, and other objects illustrative of natural history. The collection, it is stated, comprised 1600 species of plants, of which about 300 were described for the first time. His successful labours were rewarded, and a new congenial field of work was opened to him, by his nomination by Buffon to the post of professor at the *Jardin des Plantes*, vacated in his favour by his friend, Lemonnier. The garden, says one of his biographers, now became his world. His life was thenceforth marked by few incidents. He devoted himself to his pupils, to his plants, and to the preparation of various botanical works. He purposed to publish a narrative of his African explorations, but the manuscript journal being lent to Lemonnier, and by him to the king, Louis XVI., was lost, and only a few fragments of the narrative appeared. His great work is entitled *Flora Atlantica sive historia plantarum quae in Atlantide, agio Tunetano et Algeriensi crescunt*. It was published in 2 vols. 4to in 1798, and is esteemed for the singular clearness and precision of its descriptions and its nomenclature. Desfontaines, as a recluse student, escaped the perils of the Reign of Terror. On two occasions he courageously quitted his retirement to rescue the naturalists Ramond and Lheritier from prison and from death. He was admitted to the Legion of Honour at the time of its establishment. At the age of sixty-three he married a young wife, but the prospect of happiness thus opened was soon closed by her death. In 1831 he became blind, and was reduced to the recognition of his favourite plants by touch alone. Desfontaines was author of many valuable memoirs on vegetable anatomy and physiology, descriptions of new genera and species, &c., contributed to learned societies and scientific journals. One of the most important was the "Memoir on the Organization of the Monocotyledons," which gave him a

high place among discoverers. He published in 1804 a *Tableau de l'école botanique du muséum d'histoire naturelle de Paris*, of which a third edition appeared in 1831, under the new title *Catalogus Plantarum Horti Regii Parisiensis*. His modesty, simplicity of life, and good humour endeared him to his friends and to his pupils. He died at Paris on the 16th November 1833, a daughter surviving him. His Barbary collection was bequeathed to the museum, and his general collection passed into the hands of the botanist Webb.

DESHOULIÈRES, ANTOINETTE DU LIGIER DE LA GARDE (1634–1694), a French poetess, born at Paris, was the daughter of the Chevalier de la Garde, *maître d'hôtel* to the queens Mary de' Medici and Anne of Austria. She received a careful and very complete education, acquiring while still young a knowledge of Latin, Spanish, and Italian, and studying prosody under the direction of the poet Hesnaut. At the age of eighteen she married the Seigneur Deshoulières, who had soon afterwards to go abroad along with the prince of Condé on account of his complicity in the Fronde. Madame Deshoulières returned for a time to the house of her parents, where she gave herself to writing poetry and studying the philosophy of Gassendi. She rejoined her husband at Rocroi, near Brussels, where, being distinguished for her personal beauty, she became the object of embarrassing attentions on the part of the prince of Condé, against which, however, she knew how to protect herself. Having made herself obnoxious to the Government by her urgent demand for the arrears of her husband's pay, she was imprisoned in the chateau of Wilworden, the hardships being increased by the refusal of all books except the Bible and some volumes of the fathers. After a few months she was freed by her husband, who attacked the chateau at the head of a small band of soldiers. An amnesty having been proclaimed, they returned to France, where Madame Deshoulières soon became a conspicuous personage at the court of Louis XIV. and in literary society. She won the friendship and admiration of the most eminent literary men of the age—some of her more zealous flatterers even going so far as to style her the tenth muse, and the French Calliope. Her poems were very numerous, and included specimens of nearly all the minor forms, odes, eclogues, idylls, elegies, chansons, ballads, madrigals, &c. Of these the idylls alone, and only some of them, have stood the test of time, the others being entirely forgotten. She wrote several dramatic works, the best of which do not rise to mediocrity, and the worst of which are worthy of the taste that could prefer the *Phédre* of Pradon to that of Racine. Voltaire pronounced her, nevertheless, the most successful of the female poets of France; and her reputation with her contemporaries is indicated by her election as a member of the Academy of the Ricovrati of Padua, and of the Academy of Arles. In 1688 a pension of 2000 livres was bestowed upon her by the king, and she was thus raised from the poverty in which she had long lived. She died at Paris on the 17th February 1694. Complete editions of her works were published at Paris in 1797 and 1799. These include a few poems by her daughter Antoinette Thérèse Deshoulières (1662–1718), who inherited her talent.

DESIDERIO DA SETTIGNANO, sculptor, was born nearly at the beginning of the 15th century, and died in all probability in 1485. Vasari's statement, that he died at the age of twenty-eight, is altogether a mistake. Settignano is a village on the southern slope of the hill of Fiesole, still surrounded by the quarries of sandstone of which the hill is formed, and still inhabited, as it was 400 years ago, by a race of "stone-cutters," several of whom, though not disdaining the title of "lapicida," earned for themselves honoured places in the roll of Florentino

sculptors Desiderio was for a short time a pupil of Donatello, and he seems to have worked also with Mino da Fiesole, with the delicate and refined style of whose works those of Desiderio seem to have a closer affinity than with the perhaps more masculine tone of Donatello. Vasari especially praises the works of Desiderio for their grace and simplicity which, as the critic remarks, are a gift of nature, and can be acquired by no study. He particularly extols the sculptor's treatment of the figures of women and children, and the eulogy applies equally to the genius and manner of Mino da Fiesole. It does not appear that Desiderio ever worked elsewhere than at Florence; and it is there that those who are interested in the Italian sculpture of the Renaissance must seek the few but remarkable works of his chisel, which have survived the changes and vicissitudes of four centuries.

DES MOINES, formerly FORT DES MOINES, a city of the United States, capital of Iowa, at the confluence of the Raccoon with the Des Moines River, which is one of the right hand tributaries of the Mississippi, and is navigable thus far for steamboats. Its public buildings include the old capitol, erected in 1856, the new capitol, founded in 1870, the post-office, with a number of other United States offices under the same roof, the Baptist college, 15 churches, and 5 high schools; and among its industrial establishments are a paper-mill, a woollen factory, an oil-mill, besides foundries, machine-shops, flour-mills, and plough-factories. There are two public libraries in the town, one of which is maintained by the State, and numbers 15,000 volumes, and, besides several daily and weekly newspapers, no fewer than six monthly periodicals are published. Forty acres of ground have been appropriated for a public park; and another area of 100 acres belongs to a park-company. Coal, lime, and clay are abundant in the neighbourhood, and the town is supplied with water from the Raccoon. Des Moines, which dates from 1846, received incorporation in 1851, and was raised to the rank of a city and the capital of the State in 1857. Population in 1860, 3965; in 1873, 15,601.

DESMOULINS, LUCIE SIMPLICE CAMILLE BENOIST (1760-1794), was born at Guise, in Picardy, on the 2d of March 1760. His father was lieutenant-general of the bailiwick of Guise, and was desirous that Camille his eldest son, who from his earliest years gave signs of unusual intelligence, should obtain as complete an education as France could then bestow. His wishes were seconded by a friend obtaining a "bourse" for the young Desmoulins, who at the age of fourteen left home for Paris, and entered the college of Louis le Grand. In this school, in which Robespierre was also a bursar and a distinguished student, Camille laid the solid foundation of his learning, and made an acquaintance with the literature and history of the classical nations so deep and extensive that it furnished him throughout the whole of his short and chequered life with illustrations which he applied with brilliancy and effect to the social manners and political events of his time.

Desmoulins having been destined by his father for the law, and having completed his legal studies, was admitted an advocate of the Parliament of Paris in 1785. His professional success was not great; his manner was violent, his appearance far from attractive, and his speech was unpaired by the natural defect of a painful stammer. He indulged and fostered, however, his love for literature, he was closely observant of the course of public affairs, and he was thus gradually being prepared for the main duties of his life—those of a political *littérateur*.

In March 1789 Desmoulins began his political career. Having been nominated deputy from the bailiwick of Guise, he appeared at Laon as one of the commissioners for the election of deputies to the States General summoned by

royal edict of 24th January. Camille heralded its meeting by his *Ode to the States General*. It is, moreover, highly probable that he was the author of a radical pamphlet entitled *La Philosophie au peuple Français*. His hopes of professional success were now scattered, and he was living in Paris in extreme poverty and almost in squalor. He, however, shared to the full the excitement which attended the meeting of the States General. As appears from his letters to his father, he watched with exultation the procession of deputies at Versailles, and with violent indignation the events of the latter part of June which followed the closing of the Salle des Menus to the deputies who had named themselves the National Assembly. It is further evident that Desmoulins was already sympathizing, not only with the enthusiasm, but also with the fury and cruelty, of the Parisian crowds.

The sudden dismissal of Necker by Louis was the event which brought Desmoulins to fame. On the 12th of July 1789 Camille, leaping upon a table in one of the cafés of the Palais Royal, startled a numerous crowd of listeners by the announcement of the dismissal of their favourite. Losing in his violent excitement the stammer which impeded his ordinary speech, he inflamed the passions of the mob by his burning words and his call "To arms!" "This dismissal," he said, "is the tocsin of the St Bartholomew of the patriots." Drawing, at last, two pistols from under his coat, he declared that he would not fall alive into the hands of the police who were watching his movements. He descended amid the embraces of the crowd, and his cry "To arms!" resounded on all sides. This scene was the beginning of the actual events of the Revolution. Following Desmoulins the crowd surged through Paris, procuring arms by force; and on the 13th it was partly organized as the Parisian militia which was afterwards to be the National Guard. On the 14th the Bastille was taken.

Desmoulins may be said to have begun on the following day that public literary career which lasted till his death. In May and June 1789 he had written *La France libre*, which, to his chagrin, his publisher refused to print. The taking of the Bastille, however, and the events by which it was preceded, were a sign that the times had changed; and on the 15th of July Desmoulins's work was issued. It attracted immediate attention. By its erudite, brilliant, and courageous examination of the rights of king, of nobles, of clergy, and of people, it attained a wide and sudden popularity; it secured for the author the friendship and protection of Mirabeau, and the studied abuse of numerous royalist pamphleteers. Shortly afterwards, with his vanity and love of popularity inflamed, he pandered to the passions of the lower orders by the publication of his *Discours de la lanterne aux Parisiens*, which with an almost splendid reference to the excesses of the mob he headed by a quotation from St John, *Qui male agit odit lucem*. Camille was dubbed "Procureur-général de la lanterne."

In November 1789 Desmoulins began his career as a journalist by the issue of the first number of a weekly publication—*Révolutions de France et de Brabant*. He conducted this alone till July 1790, and thereafter with the assistance of Stanislas Fréron till July 1792, when the publication ceased. Success attended the *Révolutions* from its first to its last number, Camille was everywhere famous, and his poverty was relieved. These numbers are valuable as an exhibition not so much of events as of the feelings of the Parisian people during the most stormy period of their history; they are adorned, moreover, by the erudition, the wit, and the genius of the author, but they are disfigured, not only by the most biting personalities and the defence and even advocacy of the excesses of the mob, but by the entire absence of the forgiveness and

pity for which the writer was afterwards so eloquently to plead.

Desmoulins had now become an acknowledged leader of public opinion. Its sudden changes suited his fickle temperament, and form the only excuse for the glaring inconsistencies which disfigure his published writings. Mirabeau, for instance, whose genius and hospitality he had frequently and openly landed, he afterwards thought fit to denounce as the "god of orators, liars, and thieves." He was powerfully swayed by the influence of more vigorous minds, and for some time before the death of Mirabeau, in April 1791, he had begun to be led by Danton, whom he remained associated during the rest of his life.

In July 1791 Camille appeared before the municipality of Paris as head of a deputation of petitioners for the deposition of the king. In that month, however, such a request was dangerous, there was excitement in the city over the presentation of the petition, and the private attacks to which Desmoulins had often been subject were now followed by a warrant for the arrest of himself and Danton. Danton left Paris for a little, Desmoulins, however, remained there, appearing occasionally at the Jacobins club. He resigned his functions as a journalist, and the issue of his *Révolutions* ceased.

Three months afterwards, however, he again appeared in public, having been appointed secretary to the Society of the Friends of the Constitution. His second attempt at journalism was made in April and May 1792, in the issue of several numbers of the *Tribune des Patriotes*, but success did not attend the effort, and it was in his pamphlet *Jean Pierre Brissot démasqué*, which abounded in the most violent personalities, that Desmoulins again secured the eager attention of the public. This pamphlet, which had its origin in a petty squabble, was followed in 1793 by a *Fragment de l'histoire secrète de la Révolution*, in which the party of the Gironde, and specially Brissot, were most mercilessly attacked.

On the nomination of Danton, after the excesses of the 10th of August 1792, to the post of minister of justice, Desmoulins was appointed his secretary general. On September the 8th he was elected one of the deputies for Paris to the lately created National Convention. He was not successful as an orator. He was of the party of "the Mountain," and voted for the abolition of royalty and the death of the king. With Robespierre he was now more than ever associated, and the *Histoire des Brissotins*, the fragment above alluded to, was inspired by the arch-revolutionist. The success of the brochure, so terrible as to send the leaders of the Gironde to the guillotine, alarmed Danton and the author. Not so with Robespierre; and the split was formed which was to end in the ruin of the Dantonists.

In December 1793 was issued the first number of the *Vieux Cordelier*, by which Danton's idea of a committee of clemency was formulated and upheld. From the first Robespierre, although revising the sheets, disapproved of it, and at the fifth number the actual rupture became visible. Robespierre took advantage of the popular indignation roused against the Hébertists to send them to death, but the time had come when Saint Just and he were to turn their attention not only to *les enragés*, but to *les indulgents*—the powerful faction of the Dantonists. On the 7th of January 1794 Robespierre, who on a former occasion had defended Camille when in danger at the hands of the National Assembly, in addressing the Jacobins club counselled not the expulsion of Desmoulins, but the burning of certain numbers of the *Vieux Cordelier*. Camille sharply replied that he would answer with Rousseau,—"burning is not answering," and a bitter quarrel thereupon ensued. By the end of March not only

were Hébert and the leaders of the extreme party guillotined, but their opponents, Danton, Desmoulins, and the best of the moderates were arrested. On the 31st the warrant of arrest was signed and executed, and on the 3d, 4th, and 5th of April the trial took place before the Revolutionary Tribunal. It was a scene of terror not only to the accused but to judges and to jury. The retorts of the prisoners were notable. Camille on being asked his age, replied, "I am thirty-three, the age of the *sans-culotte* Jesus, a critical age for every patriot." This was false, he was thirty-four.¹ Tinville, alarmed at the eloquence of Danton, procured from the Committee of Public Safety a decree which closed the mouths of the accused. Armed with this and the false report of a spy who charged the wife of Desmoulins with conspiring for the escape of her husband and the ruin of the republic, Tinville by threats and beseechings at last obtained from the jury a sentence of death. It was passed in absence of the accused, and their execution was appointed for the same day.

Since his arrest the courage of Camille had miserably failed. He had exhibited in the numbers of the *Vieux Cordelier* almost a disregard of the death which he must have known hovered over him. He had with consummate ability exposed the terrors of the Revolution, and had adorned his pages with illustrations from Tacitus, the force of which the commonest reader could feel. In his last number, the seventh, which his publisher refused to print, he had dared to attack even Robespierre, but at his trial it was found that he was devoid of physical courage. He had to be torn from his seat ere he was removed to prison, and as he sat next to Danton in the tumbrel which conveyed them to the guillotine, the calmness of the great leader failed to impress him. In his violence, bound as he was, he tore his clothes into shreds, and his bare shoulders and breast were exposed to the gaze of the surging crowd. Of the fifteen guillotined together, including among them Hérault de Séchelles, Westermann, and Philippeaux, Desmoulins died third, Danton, the greatest, died last. With them also died the hope of the Revolution. But a few months were to pass ere it was to be solemnly decreed that they had "deserved well of humanity."

On the 29th of December 1790, Camille had married Lucile Duplessis, and among the witnesses of the ceremony are observed the names of Brissot, Pétion, and Robespierre. The only child of the marriage, Horace-Camille, was born on the 6th of July 1792. Two days afterwards Desmoulins brought it into notice by appearing with it before the municipality of Paris to demand "the formal statement of the civil estate of his son." The boy was afterwards pensioned by the French Government. Lucile, Desmoulins's accomplished and affectionate wife was, a few days after her husband, and on a false charge, condemned to the guillotine. She astonished all onlookers by the calmness with which she braved death.

See the biographies of Desmoulins by Edward Fleury and Jules Claretie. The latter, entitled *Camille Desmoulins and his Wife*, has been translated into English (London, 1876). The work of Roch Mercadier, *Histoire des hommes de proie*, is not trustworthy. See also the literature of the Revolution, and especially of the Dantonists. The standard edition of Desmoulins's works is that of Matton. (T S)

DE SOTO, FERDINANDO (1496?-1542), a Spanish captain and explorer, who is frequently accredited with the honour of being the discoverer of the Mississippi, and is certainly one of the most remarkable of the Eldorado adventurers of the 16th century. He was born at Xeres de Caballeros, in Estremadura, of an impoverished family.

¹ This is borne out by the register of his birth and baptism, and by words in his last letter to his wife,—"I die at thirty-four." The dates (1762-94) given in nearly every biography of Desmoulins are certainly inaccurate.

of good position, and was indebted to the favour of Pedrarias Davila for the means of pursuing his studies at the university. He commenced active life in 1519 by joining his patron in his second expedition to Darien, where he distinguished himself by his ability and the independence of his demeanour. In 1528 we find him exploring the coast of Guatemala and Yucatan, and in 1532 he led a reinforcement of 300 volunteers to the assistance of Pizarro in Peru. To him was due the discovery of the pass through the mountains to Cuzco; and in the capture of that city and in other important engagements he bore a brilliant part. After the completion of the conquest of De Soto, who had landed in America with "nothing else of his own save his sword and target," returned to Spain with a fortune of "an hundred and fourscore thousand ducats," which enabled him to marry the daughter of his old patron Davila, and to maintain "all the state that the house of a nobleman requireth." The Emperor Charles V., to whom he had lent a portion of his wealth, appointed him governor of the Island of Cuba, and adelantado or president of Florida, which was then the object of great interest, as possibly another Peru. In 1538 he set sail with an enthusiastic and richly furnished company of about 600 men, of whom several had sold all that they possessed to furnish their equipment. Landing in May 1539 at Espiritu Santo Bay, on the west coast of the present State of Florida, the explorers continued for nearly four years to wander from one point to another, ever deceived in their expectations, and ever allured by the report of the wealth that lay beyond. The exact line of their route is in many places difficult to identify, but it seems to have passed N. through Florida and Georgia as far as 35° N. lat., then S. to the neighbourhood of Mobile, and finally N.W. towards the Mississippi. This river was reached early in 1541, and the following winter was spent on the Washita. As they were returning in 1542 along the Mississippi, De Soto died (either in May or June), and his body was sunk in its waters. On the failure of an attempt which they made to push eastwards again, his men, under the leadership of Moscoso, were compelled in 1543 to trust themselves to the stream. A voyage of nineteen days brought them to the sea, and they then held along the coast to Panuco, in Mexico.

Of this unfortunate expedition three narratives are extant, of seemingly independent origin, and certainly of very different character. The first was published in 1557 at Evora, and professes to be the work of a Portuguese gentleman of Elvas, who had accompanied the expedition—*Relaçam verdadeira dos Trabalhos q' ho Governador dō Fernão d'Souza & certos Fidalgos Portuguezes passaram no d'acbrimento da Provincia da Florida. Agora novamente feita per hũ Fidalgo Delvas*. An English translation was published by Hakluyt in 1609, and another by an anonymous translator in 1686, the latter being based on a French version which had appeared at Paris in 1685 from the pen of Citri de la Guette. The second narrative is the famous history of Florida by the Inca, Garcilasso de la Vega, who obtained his information from a Spanish cavalier engaged in the enterprise; it was completed in 1591, first appeared at Lisbon in 1605 under the title of *La Florida del Ynga*, and has since passed through many editions in various languages. The third is a report presented to Charles V. of Spain in his Council of the Indies in 1544, by Luis Hernandez de Biedma, who had accompanied De Soto as His Majesty's factor. It is to be found in Ternaux-Compan's *Recueil de Pièces sur la Floride* in the *Historical Collections of Louisiana*, Philadelphia, 1860, and in W. B. Rye's reprint for the Hakluyt Society of Hakluyt's translation of the Portuguese narrative.

See Baneroff's *History of the United States*, vol. 1, McCulloch, *Researches Concerning the Aboriginal History of America*, Monette, *History of the Discovery and Settlement of the Valley of the Mississippi*.

DESSAIX, JOSEPH MARIE, COUNT (1764–1834), French general, was born at Thonon, in Savoy, September 24, 1764. He studied medicine, took his degree of doctor at Turin, and then went to Paris. When the Revolution

broke out he served in the National Guard. Sympathizing with the extreme party, he attempted in 1791 to establish its principles in his native land; but, being prosecuted by order of the king, he escaped to France. He had organized the so-called *Legion of the Allobroges*, and as its captain took part in the great conflict of August 10, 1792. In the following years he served at the siege of Toulon, in the army of the eastern Pyrenees, and in the army of Italy. He was captured at the battle of Rivoli, but was soon exchanged. In the spring of 1798 Dessaix was elected member of the Council of Five Hundred. In consequence of his opposition to the revolution of 18 Brumaire (9th November 1799), by which Napoleon became supreme, he was excluded from the council, retaining, however, his military command. He was appointed successively commander of Frankfort and of Breda, and in September 1803 was promoted general of brigade, and soon after commander of the Legion of Honour. He distinguished himself at the capture of Ulm, at the passage of the Tagliamento, and at the battle of Wagram. His brilliant courage at this battle procured him from the emperor the surname of "the Intrepid," and the dignity of count of the empire. He was also promoted general of division, and named grand officer of the Legion of Honour. He took part in the expedition to Russia, and was twice wounded. For several months he was commander of Berlin, and afterwards delivered the department of Mont Blanc from the Austrians. His just conduct on this occasion earned him the title of the Bayard of Savoy. After the first restoration, Dessaix was created chevalier of St. Louis. He nevertheless joined Napoleon in the campaign of the Hundred Days, and in 1816 was imprisoned for five months. The rest of his life was spent in retirement. He died October 26, 1834.

DESSAU, the chief town of the duchy of Anhalt, in North Germany, is situated in 51° 51' 6" N. lat. and 12° 18' E. long., on the left bank of the Mulde, nearly two miles from its confluence with the Elbe, and 67 miles south-west of Berlin, with which it is connected by railway. The town has three suburbs. Of its gates the Zerbster Thor, with the statues of Otto the Rich and Albert the Bear, alone remains. The ducal palace, which stands in fine pleasure-grounds, contains a collection of historical curiosities, and a gallery of pictures, including works by Cimabue, Lippi, Rubens, Titian, and Vandyck. Among the other buildings are the palace of the hereditary prince, the theatre and concert room, the administrative offices, bank, gymnasium, musical academy, Amelia and Wilhelmine Institutes, two hospitals, and the Schlosskirche, adorned with paintings by Lucas Cranach, in the most interesting of which (the Last Supper) are portraits of several Reformers. The manufactures of Dessau are woollen, linen, and cotton goods, hats, leather, tobacco, and organs and other musical instruments; and there is a considerable trade in corn. In the environs are the ducal villas of Georgium and Luisium, the gardens of which, as well as those of the neighbouring town of Worlitz, are much admired. Dessau was probably founded by Albert the Bear; it was already a town in 1213. It first began to grow into importance at the close of the 17th century, in consequence of the religious emancipation of the Jews in 1686, and of the Lutherans in 1697. Moses Mendelssohn, the philosopher, was born at Dessau in 1729. The population in 1875 was 19,621.

DESTERRO, NOSSA SENHORA DO DESTERRÔ, or SANTA CATHARINA, a city of Brazil, the chief town of the province of Santa Catharina, on the west coast of the island from which the province derives its name, in 27° 30' S. lat. and 48° 30' W. long. It is a small but strongly fortified place, with an excellent harbour, some foreign commerce, and regular intercourse with Rio de Janeiro, from which it

is distant about 460 miles. Its public buildings include a governor's palace, an arsenal, a court-house, and a hospital, but none of them have any architectural interest. In 1838 great damage was done to the town by a waterspout. Population from 7000 to 8000.

DETMOLD, the chief town of the principality of Lippe, in North Germany, is situated on the Weire, at the foot of the Teutoburger-Wald, in $51^{\circ} 56' N.$ lat. and $8^{\circ} 50' E.$ long. The foundations of the older portion of the town were laid in 1300, and those of the newer in 1709. Among the chief buildings and institutions are the new palace, in the Renaissance style, erected about 1550, the town-house, house of correction, penitentiary, military hospital, gymnasium, the industrial, commercial, and free schools, the theatre, museum of natural science, and public library. The leading industries are linen-weaving, tanning, brewing, horse-dealing, and the quarrying of marble and gypsum. About three miles to the south-west of the town is the Groteuburg, with Bandel's colossal statue of Hermann or Arminius, the leader of the Cherusci. Detmold (Thiattmelli) was in 783 the scene of a conflict between the Saxons and the troops of Charlemagne. The population in 1875 was 6982.

DETROIT, the most important city of Michigan, in the United States of America, capital of Wayne county, situated on the west bank of the Detroit River (from the French for a strait), opposite the Canadian town of Windsor

It is about 7 miles S.W. of Lake St Clair, 55 miles from Lake Huron, and 18 miles N. of Lake Erie, in $42^{\circ} 20' N.$ lat. and $83^{\circ} 3' W.$ long. The river, which there separates the United States from Canada, is about half a mile to three quarters of a mile wide, and $5\frac{1}{2}$ fathoms deep, and flows with a pretty swift current. The population of Detroit has increased from 21,019 in 1850 to 45,619 in 1860, and 79,577 in 1870. Of this last number 35,381 were of foreign birth, including 12,647 Germans. According to the State census of 1874, the population of the city was 101,255; while in the neighbouring towns are not fewer than 15,000 persons whose business interests are in the city. Detroit with its suburbs stretches about five miles along the river, and the central part extends for about two miles back from the shore. The streets generally cross each other at right angles, and are from 50 to 100 feet wide. They are for the most part ornamented with rows of trees. A number of avenues, from 100 to 200 feet wide, diverge from the Grand Circus, a spacious park, semi-circular in form, which is divided into two quadrants by Woodward Avenue. Connected with the Grand Circus is

the Campus Martius, a public "place" about 600 feet long and 250 feet wide. The chief public building is the city hall, which faces the Campus Martius with fronts on four streets, and is one of the finest structures of the kind in the West. Built of sandstone, and designed after the Italian style of architecture, it measures 200 feet long, and 90 feet wide, and is surmounted by a tower 180 feet high. The cost of the building amounted to \$600,000 (£120,000). Other noteworthy structures are the opera house, the office of the Board of Trade, the Roman Catholic cathedral, which is the most imposing of the many churches in the city, the custom house, containing also the post-office, and the Michigan Central Railroad freight depot, which is 1250 feet long by 102 feet wide. On the Campus Martius stands the Michigan Soldiers' and Sailors' Monument. It is of bronze and granite, 55 feet high and about 20 feet in diameter at the base. It is surmounted by a colossal bronze statue of an Indian girl representing Michigan in defence of the Union. The design comprises numerous other bronze figures, all of which were cast in Munich.

The commercial facilities of Detroit are very extensive. The Detroit River is a connecting link in the great chain of lake navigation, and affords the best harbour on the lakes. The city is the centre of an extensive railroad system, which presents important channels of transportation in almost every direction. Not fewer than five trunk lines diverge to the eastern seaboard. More than 350 vessels are owned here, and from ten to thirteen daily lines of steamers run to various points on the lakes. There is a considerable foreign commerce with Canada, the imports in 1875 amounting to \$1,680,922, and the exports to \$2,340,015; 4126 vessels entered and 4355 cleared in the foreign trade; 3968 entered and 3000 cleared in the coastwise trade. The large quantities of produce, chiefly from Michigan, passing eastward through the city by rail and water, give to Detroit an extensive domestic commerce. The manufacturing industries of the city are extensive and important. The working of iron is carried on in numerous blast furnaces, foundries, and other establishments. In 1875, 9 mills manufactured 238,200 barrels of flour, 3 factories produced more than 4,000,000 lb of chewing and smoking tobacco; and 171 establishments made about 30,000,000 cigars. Twelve saw-mills annually cut from 45,000,000 to 50,000,000 feet of lumber, and 26 brick-yards make from 55,000,000 to 60,000,000 bricks a year. The extensive Pullman car works, with a capital of about \$12,000,000, are situated here; also one of the seven pin factories in the United States. The city glass works produce about \$200,000 worth of glass a year; and the copper smelting works more than \$2,000,000 worth of ingot copper from Lake Superior ore. There are four ship-yards and three large dry docks.

Detroit has 10 lines of street railway, with more than 45 miles of track intersecting the city in every direction. It is divided into 11 wards, each returning 2 aldermen to the city council, and has a metropolitan police of 100 members, 7 steam fire-engines, the stations of which are connected by telegraphic alarm apparatus with all parts of the city; and ample supplies of water from the river. There are 64 churches, 14 asylums and hospitals, 18 public schools, 4 public libraries, the largest containing about 25,000 volumes; 2 medical colleges, and 3 medical societies; 8 daily newspapers, and 30 weekly and monthly papers and periodicals; several public parks; 10 banks, with an aggregate capital of \$3,210,000; and 62 incorporated companies, representing capital stock to the amount of \$22,445,000. The net city debt proper, January 1, 1875, amounted to \$990,340, or about \$9.78 per head of the population.

and in 1868 transformed into a court-house, Alexander's Church, with the ducal burial-place, and the church which was built by Charles XI. of Sweden. The industry of the inhabitants is mainly devoted to the manufacture of cotton, silk-plush, tobacco, and oil. Population in 1875, 9349.

Deux Ponts, which derives its name from the two bridges over the Erbrich, was before 1394 the seat of an imperial countship. On the partition of the Palatinate, with which it had been incorporated, it became in 1410 an independent duchy, which in 1654 furnished a king to Sweden in the person of Charles Gustavus. The death of Charles XII. in 1718 broke its connection with the Swedish crown, and the extinction of the Klenburg line, to which it was next transmitted, passed it on to the present ruling family of Bavaria. In literary history it is interesting as the place where the Bypontine editions of the Greek, Latin, and French classics were published by a learned society in the latter part of the 18th century. See J. C. Crollius, *Origines Bypontine*, 1761–1769; Lehmann, *Vollständige Geschichte des Herzogthums Zweibrücken*, Munich, 1867.

DEVAPRAYAGA, a town of British India, in the presidency of Bengal and province of Gurhwal, in 30° 9' N. lat. and 78° 39' E. long. It is one of the five sacred towns of the Hindus,—a pre-eminence which it owes to its position at the confluence of the Alakamunda and the Bhagirathi, whose united waters constitute the Ganges proper. It stands at an elevation of 2266 feet above the sea.

DEVELOPMENT. See EMBRYOLOGY and EVOLUTION.

DEVENTER, or, by corruption, DEXTER, a town of Holland, in the province of Overijssel, about 25 miles north of Arnheim, on the right bank of the Yssel, which there receives the waters of the Schipbeek, and is crossed by a bridge of boats. It is a clean, prosperous place, and at the same time preserves a large number of ancient buildings as well as its fortifications. Of special interest are the Protestant church of St. Leiviu, which dates from 1334, occupies the site of an older structure of the 11th century, and possesses some fine stained glass; the Roman Catholic *Broekerkerk*, with three ancient gospels; the *Bergkerk*, which belonged to the Premonstratensians; the town-hall, built in 1693, containing a remarkable painting by Terburg, who was for some time burgomaster of the town; and the weigh-house, which dates from 1528. There are also cavalry-barracks, an arsenal, a court-house, a hospital, and a lunatic asylum, while among the scientific and educational institutions, an observatory, a gymnasium, and a high school may be mentioned. The last, known as the "Athenaeum" down to 1864, dates from 1830, and has a library of 6000 volumes, inclusive of a number of Oriental MSS., several *incunabula*, and a 13th century copy of *Reynard the Fox*. The archives of the town are of considerable value from the fact that it was the chief town of a province. Besides a good agricultural trade, the inhabitants carry on the weaving of carpets, woollens, and silks, cotton-printing, and iron-founding; and their honey-cakes are exported in large quantities to all parts of the Netherlands. Population in 1869, 17,983.

Deventer is mentioned in 778 in connection with a Saxon invader, but its importance only dates from the 11th century. In 1123 it was relieved by the emperor Henry V from an investment by the duke of Saxony and the bishop of Munster. To Queen Eleanor of England it was indebted for the monastery of the Récollets, and in 1366 she breathed her last within its walls. During the War of Independence it was treacherously surrendered to the Spaniards by Edward Stanley, an Englishman, but was recaptured in 1591 by Prince Maurice of Orange. Its bishopric, which had been established only in 1569, was then abolished, and in the following year it was found necessary to destroy its wooden bridge over the Yssel. In 1813 it was invested by the Allies, and in 1814 the French withdrew in terms of the peace.

DEVEREUX. See ESSEX, EARLS OF.

DE VIGNY, ALFRED VICTOR, COUNT (1797–1863), a distinguished French poet and novelist, was born at Loches, in Touraine, March 27, 1797 (or 1799). His father, a man of noble descent, was a cavalry officer, who

had served with distinction in the Seven Years' War. His mother was the daughter of an admiral. Tales of military achievements and traditions of the *ancien régime* were familiar to him in his childhood, and furnished the most powerful influences towards the formation of his character and the direction of his early ambition. He received his education at Paris, at the school of M. Hix; but, his royalist sympathies being threatened by the prevailing admiration for the empire, he was removed and placed under a private tutor. After the first restoration of the Bourbons he was admitted, at the age of sixteen, into the musqueteers of the royal household, and in this capacity he accompanied the royal family to Ghent in 1815. In the following year, on the suppression of the musqueteers, he passed into the royal guard. He remained in the army about thirteen years, and attained the rank of captain, but without seeing active service, and, wearied with the dullness of the life which he had desired, resigned his commission in 1827. He had not long before married a rich English lady. The leisure of his soldier-life had not been wasted. Not only was he gaining knowledge by observation of men and experience of life, but he meditated much, and, as he says, had all his works in his head,—"*ils marchaient avec moi . . . et quand on m'arrêtait, j'écrivais.*" His first publication was a volume of poems, which appeared in 1822. Some of these had already been published in periodicals; and he was therefore starting on his poetical career about the same time that Victor Hugo was writing his earliest *Odes* and Lamartine his earliest *Méditations*. Two years later (1824) he published the poem of *Eloa*, a graceful embodiment of a delicate fancy. It is the story of a bright creature, "sister of the angels," born of a tear of the Saviour, and whose tender pity for the evil spirit becomes the occasion of her own fall. This was followed by several other poems, *Le Déluge*, *Moïse*, *Dolorida*, &c. In these later pieces De Vigny shows himself to have been under the powerful influence of Victor Hugo. Hitherto, however, notwithstanding the evident tokens of his genuine inspiration as a poet, he had not attained general recognition. This he first secured, won it even by storm, by the publication, in 1826, of his historical romance, *Cing-Mars*, the story of a conspiracy under Louis XIII. This work appeared one year before Manzoni's famous novel, *I Promessi Sposi*; and both works were among the most noteworthy productions of the school of Walter Scott, whose Continental reputation was then at its height. The book had an immense run, and passed through many editions. In its pages the author shows himself qualified to present in a masterly and truthful way the character of an age, to draw vigorous portraits of great historical figures, and to depict feeling with delicacy and simplicity. It was about this time that De Vigny's friendship with Lamartine began. He was now one of the recognized chiefs of the new school, the Romantics, and one of the editors of the *Muse française*. In 1829 he produced a translation of *Othello*, which was acted at the Théâtre Français, but was not very warmly received. His next dramatic attempt was *La Maréchale d'Ancre*, performed at the Odéon in 1831. It is characterized as a learned study of the period, wanting the breath of life and the fire of poetic passion. These qualities were present in superabundance in his next and last dramatic work, *Chatterton*, produced in 1835. Although faulty in construction, and better fitted for the closet than for the stage, this powerful play has kept its place in the theatrical repertory. De Vigny's remarkable prose work, entitled *Stello, ou les Diables bleus*, appeared in 1832. It consists of three biographical studies, the subjects of which are three unfortunate poets, Gilbert, Chatterton, and André Chénier, whose fate is narrated to Stello, an invalid poet, by a philosophical physician, le

docteur noir. True in spirit while inaccurate in detail, these stories, exquisitely told, are intended to teach poets the lesson of self-renunciation. Stello was followed, in 1835, by another prose work of equal, perhaps superior, literary merit, entitled *Servitude et grandeur militaire*. This too, like Stello, is composed of three stories; and in these is depicted the soldier's life, his sufferings, his duty, and his true reward. "The poem of human life," says J. S. Mill, in his review of De Vigny's works (*Dissertations*, vol. 1), "is opened before us, and M. de Vigny does but chant from it, in a voice of subdued sadness, a few strains telling of obscure wisdom and unrewarded virtue,—of those antique characters which, without self-glorification or hope of being appreciated, carry out, as he expresses it, 'the sentiment of duty to its extremest consequences.'" De Vigny's latest gift to the world was his *Poemes philosophiques*, or *Les Destinées*, part of which appeared in his life-time in the *Revue des Deux Mondes*, the rest, with these, were published after his death by his literary executor. These poems are mainly utterances of unbelief and despondency, intermixed with exhortations to a stoical resignation and self-reliance. De Vigny was received at the French Academy in January 1816, but, in consequence of the coldness of the reception and the offensive speech of M. Molé on the occasion, he refused to be presented to the king. He died at Paris, after severe and prolonged sufferings bravely borne, September 17, 1863. (W.L.N.C.)

DEVIL is the name which has been given in the New Testament and in Christian theology to a supreme evil personality supposed to rule over a kingdom of evil spirits, of whom he is the chief, and to be the restless and unflinching adversary of God and man. The Hebrew term denoting "adversary," or *Satan*, is also applied to this supreme evil spirit, or prince of the kingdom of evil. There can be no question that such an evil spirit is frequently spoken of in the New Testament. He is designated by various names in addition to these mentioned, such as "the Tempter," "Beelzebub," "the Prince of Devils," "the Strong One," "the Wicked One," "the Enemy," or "the Hostile One." Throughout the Gospels these terms are used interchangeably, and in all cases seem to denote the same active power or personality of evil outside man and exercising influence over him. It may be a question how far Jesus Christ himself acknowledges the existence of such an evil power, but there can be no question that such a being was recognized in the current belief of the Jews in His time.

But it is also certain that this belief amongst the Jews was one of gradual growth, and is not to be traced in the Old Testament in any such definite form as we meet with it in the New. The expression "Satan" is indeed found in the Old Testament, but only five times, if so frequently, as a proper name,—thrice in the book of Job (i. 6, 12, ii. 1), once in the opening of the 21st chap. of 1 Chronicles (although here the allusion to a distinct personality may be held doubtful), and in Zechariah (iii. 1). In all other places where the word occurs, "Satan" is used in its common sense of "adversary," a sense in which it also occurs in the Gospels, in the well-known passage (Matt. xvi. 23) where our Lord addresses St. Peter, "Get thee behind me, Satan," or "adversary." The books of Chronicles and Zechariah are indisputably amongst the latest writings of the Old Testament; and, although the date of Job is unsettled, it may also be presumed to belong to a late period in the history of revelation. In the earlier prophetic literature of the Hebrews there is no recognition of any spirit of evil at war with Jehovah. All power and dominion are, on the contrary, clearly ascribed to Jehovah himself, who is supreme in heaven, on earth, and under

the earth. The connection of Satan with the serpent in the garden of Eden in Genesis (iii. 1-7) is an inference of later dogmatic opinion, arising probably out of the use of the expression "Old Serpent" applied to Satan in Rev. (xx. 2), but receives no countenance from the scriptural narrative itself, which speaks of the serpent purely as an animal, and pronounces a curse against him with reference to his animal nature solely. The idea of a distinct personality of evil, therefore, is not to be found in the earlier Hebrew Scriptures, and is, in fact, inconsistent with the cardinal principle of the older Hebrew theology that Jehovah was the sole source of all power, the author both of good and evil, who hardened Pharaoh's heart (Exod. x. 27), and sent a lying spirit among the prophets of Ahab (1 Kings xxii. 20-3). Even in the later Scriptures in which "Satan" is spoken of as a distinct person, there is little or no analogy betwixt what is said of such a person in these Scriptures and what is said of him in the New Testament. The "Satan" of the book of Job is described as coming among the "sons of God" to present himself before the Lord. He is the image of malice, restlessness, and envy—the willing messenger of evil to Job; but he is not represented as the impersonation of evil, or as a spiritual assailant of the patriarch. He is really a delegated agent in the hands of Jehovah to execute His will, and the evils with which he assails Job are outward evils. The picture is quite different from that of the "Archangel ruined," or the devil, or Satan, of later theology.

The question then arises as to the special source of the conception of the devil as a fallen and evil spirit. The explanation commonly given of this conception by our modern critical schools is that it sprang out of the intercourse of the Jews with the Persians during their period of exile. In the Persian, or Iranian, mythology it is well known that a personal power of evil was conspicuously recognized. The Iranian religion divided the world betwixt two opposing self-existent deities, the one good and the other evil, but both alike having a share in creation and in man. Ormuzd, or Ahuramazda, was holy and true, and to be honoured and worshipped. But Ahriman, or Anra-mainyu, the evil-minded, the spirit of darkness, was no less powerful, and claimed an equal share of man's homage. These were the good and the evil in thought, word, and deed. Man has to choose betwixt the two. He cannot serve both. With this dualistic system the Jews came in contact during their captivity at Babylon, and are supposed to have retained permanent traces of it in their subsequent theology. The conception of the devil, and of a lower kingdom of demons, or devils, is the evident illustration of this. The case is put in this way by a Christian writer of moderation and knowledge:—"That the Hebrew prophets had reiterated their belief in one God with the most profound conviction is not to be questioned; but as little can it be doubted that, as a people, the Jews had exhibited little impulse towards monotheism, and that from this time (the period of their captivity) we discern a readiness to adopt the Zoroastrian demonology" (Cox's *Iranian Mythology*, p. 356). The conception of Satan in the later canonical books of Chronicles and Zechariah is even attributed to this source. "Thus far Satan had appeared, as in the book of Job, among the ministers of God, but in later books we have a closer approximation to the Iranian creed. In Zechariah and the first book of Chronicles, Satan assumes the character of Ahriman, and appears as the author of evil. Still later he becomes the prince of devils, the source of wicked thoughts, the enemy of the Word and Son of God" (*Ibid.*, p. 351).

The process by which the Jewish mind worked out this conception and the whole scheme of demonology found in the New Testament was of course gradual. The Book of

Wisdom, a product of Alexandrian-Jewish thought in the 2d century before Christ, which speaks of the devil having "through envy introduced evil into the world" (ii. 24), is supposed to represent a stage in this development; and the apocryphal books of Enoch and Esdras (IV.), the former of which is pre-Christian, indicate further stages. Another stage is supposed to be marked by the recognition of a "devil," or evil spirit, under the name of Asmodeus, in the book of Tobit (150 B.C.) There is certainly a remarkable analogy between parts of the eschatological teaching of the book of Enoch and other apocryphal books and that of the gospels. But the development of Jewish theology as a whole, in the ages immediately antecedent to Christianity, is still involved in considerable obscurity; and it is difficult to say how much of the eschatology and demonology of the New Testament is to be regarded as original, and how much as derived or inherited from prior modes of thought.

It must also be conceded that, even should we accept the modern critical theory of the rise of the New Testament conception of the devil and of demons, there is much in it that must be pronounced very different from the Zoroastrian or Iranian conception. The devil of the gospels is in some respects very unlike the Ahriman of Zoroastrianism. He is in no sense a twin-creator of man. He has no original share in him, and no right to his homage. In the Persian system the warfare of good or evil is a warfare of balanced forces. But the evil personality of the New Testament, powerful as he is, and always the enemy of the divine, is yet a subordinated and inferior being. He is the tempter of the Son of God and the enemy of man. He has power on earth, and even a certain power over the Son of man; and yet the Son can restrain and bid him get behind Him. The subordinated forces of evil—the demons—are all subject to Christ. They hear His word and obey it. In short, the devil of the New Testament is, in comparison with the source of evil recognized by Zoroastrianism, a limited power. He is a subordinate although insurrectionary spirit, working by spiritual means upon the heart of man, and in no sense a native power having an original or creative hold of him. This sets the evangelical conception on a higher level than the Persian, and proves that the Jewish mind, supposing that it did borrow certain impulses from the Iranian dualism with which it came in contact in the period of exile, yet wrought out the conception in the depth of its own religious and moral consciousness within the sphere of revealed truth which was its great educational medium.

The idea of an evil personality was therefore so far a native growth of the Jewish mind, working upon hints contained, although not developed, in the earlier Hebrew Scriptures. It is evident from various passages, both of the Pentateuch (Lev. xvii. 17; Deut. xxxii. 17) and of the prophetic Scriptures and the Psalms (Isa. xiii. 21, xxxiv. 14; Jer. xv. 36; Ps. cvi. 37), that the Hebrews were cognizant of evil beings supposed to dwell in darkness and waste places. The names applied to those beings in the passages referred to are various, sometimes *seirim*—lit. goats (Lev. xvii. 7; Isa. xiii. 21), and sometimes *shedim* (Deut. xxxii. 17), probably a name for demigods, both phrases being translated "devils" in our authorized version of the Pentateuch. This translation suggests later associations; but such expressions plainly denote a belief in evil beings, the survival, probably, in the Hebrew consciousness of fragments of an older native faith which deified the powers of evil as well as of good. Some have traced a similar survival in the name Azazel, translated in our version scape-goat (Levit. xvi. 8, 10, 26), and which has been supposed to represent an evil being haunting the desert, to which was devoted the goat sent away on the great day of

atonement. This opinion is disputed by others on grounds both philological and theological. But it may be almost certainly assumed that, with all the jealous monotheism of the Jews, there was an undergrowth of darker conceptions, pointing to evil existences opposed to the divine, and that to some extent the later idea of the devil sprang out of this natural growth in the Hebrew mind of an evil side to nature and to life. This process of growth may have been greatly aided by contact with the Persian dualism, and especially the idea of a kingdom and hierarchy of evil powers seems to have been indebted to this source. But it was also largely original, and at the end, as at the beginning, the Jewish and Christian conceptions of the devil and his angels were very distinct from those of the Persian faith. They belong to a higher level of thought, and are the product of a more advanced stage of moral and spiritual feeling.

The idea of the devil so clearly expressed in the New Testament passed as a dominant factor into the early Christian theology, acquiring for many centuries an always deeper hold on the popular religious imagination. In the writings of the fathers of the 2d and 3d centuries the devil plays an important part. The whole of the Roman imperial system, and all that opposed the progress of the gospel, was identified with his kingdom. Satan was the "prince of this world," he was the rival and caricature of the divine. "Satan," said Tertullian, "is God's ape," and the saying passed into a proverb. He fell by pride and arrogance and envy of the divine creation (Iren., *Adv. Hær.*, iv. 40). He was, according to Cyprian (*De Unitate Eccl.*), the author of all heresies and delusions, he held man by reason of his sin in rightful possession, and man could only be rescued from his power by the ransom of Christ's blood. This extraordinary idea of a payment or satisfaction to the devil being made by Christ as the price of man's salvation is found both in Irenæus (*Adv. Hær.*, v. 1. 1.) and in Origen, and may be said to have held its sway in the church for nearly a thousand years. And yet Origen is credited with the opinion that, bad as the devil was, he was not altogether beyond hope of pardon. In this as in other respects the early Alexandrian school showed a milder and broader type of thought than the prevailing theology of the church. Occasionally in later times the milder opinion was expressed, as by Gregory of Nyssa in the 4th century; but gradually it vanished, and the devil was drawn by the theological pencil in darker and more terrible colours. Augustine greatly helped to strengthen and confirm the darker view, and to give in this as in other things a gloomier tinge to religious thought. During the Middle Ages the belief in the devil was absorbing—saints conceived themselves and others to be in constant conflict with him. It is hardly possible for us now, as M. Reville says in his short treatise on the subject, "to imagine to what a degree this belief controlled men's whole lives. It was the one fixed idea with every one, particularly from the 13th to the 15th century—the period at which we may consider this superstition to have reached its climax." The superstition showed certainly but slight signs of yielding in the 15th, or even in the 16th or 17th centuries. Luther lived in a constant consciousness of contact and opposition with the evil one. At his study, in bed, or in his cell, the devil was incessantly interfering with his work or rest. As he was going to begin his studies he heard a noise which he immediately interpreted as proceeding from his enemy. "As I found he was about to begin again, I gathered together my books and got into bed. Another time in the night I heard him above my cell walking in the cloister; but as I knew it was the devil I paid no attention to him and went to sleep." Again he says: "Early this morning, when I awoke the fiend came and began disputing with

me. 'Thou art a great sinner,' said he. I replied, 'Canst thou not tell me something new, Satan?'

This realism of belief in an evil power near to man, and constantly assailing him, continued more or less all through the 17th century, and was especially strong, as Mr Buckle has shown in his well-known volumes, in Scotland. He has somewhat overcharged his picture, but he presents at the same time indisputable facts which leave no doubt that the clergy and people alike imagined that "the devil was always and literally at hand—that he was haunting them, speaking to them, and tempting them. Go where they would he was there." With the rise of a rationalistic temper throughout Europe, in the 18th century, this belief in the pervading influence of diabolic agency began to disappear. The sense of the supernatural decayed in all directions, and especially the old belief in the arbitrary control exercised by an evil power over human destiny. And while the religious impulse has gained greatly since then, and shown renewed vigour both in an evangelical and catholic direction, it cannot be said that the earlier faith in the operations of a personal devil has acquired reascendency. It may be still the prevailing opinion of Christendom that there is an evil power working in the world opposed to the divine; but whether this power is personal, or how far it touches the human will, or again, whether there is a subterranean kingdom of demons with a prince of demons or devil at their head, and how far such a kingdom has any relation to human destiny, are all questions that must be held to be very unsettled, or maintained with very doubtful confidence in any section of the Christian church. It is our business simply to note such a change in the attitude of Christian belief, and not to express any opinion as to its advantage or otherwise. It is too much to speak with M. Reville of Satan as a "fallen majesty," but the idea of the devil certainly no longer hulks in Christian thought as it once did, nor is his reign the recognized influence that it once was over human life and experience. (J. T.)

DEVIL FISH, or SEA DEVIL. (*Lophus piscatorius*), an Acanthopterygian fish belonging to the family *Petichelidae*, so named from its hideous aspect, produced mainly by the enormous size of its head in proportion to the rest of its body. The latter tapers off rapidly towards the tail, and gives the creature the appearance of a gigantic tadpole—a resemblance to which it owes the name of frog-fish, applied to it from the earliest times. The cleft of the mouth is also exceedingly wide, measuring 14 inches in a specimen 4½ feet long, and when the month is open the lower jaw protrudes beyond the upper, while both jaws are armed with several rows of formidable teeth. The pectoral fins are broad, and are rendered conspicuous by the prolongation of the carpal bones to which they are attached; the ventral fins are palmate, and are placed far forward on the body. The sea devil is a sluggish fish, and, being at the same time exceedingly voracious, is said to have recourse to stratagem in order to satisfy its inordinate appetite. Three anterior dorsal spines, isolated from the others, and attached to the head in front of the eyes, are so modified as to form long filiform appendages, two of these being articulated to the skull by means of a bony ring, and thus capable of being moved in all directions by appropriate muscles, while the end of the front tentacle is broad and flattened, and of a shining, silvery aspect. Concealing itself in the mud of the sea-bottom, it waves these tentacles aloft, and the silvery extremity of the front filament nets as a bait in tempting the smaller fishes to approach near enough to be seized by the capacious jaws beneath. On this account the creature has received the name of angler, or fishing frog. The lobes, which form a fringe around the anterior part of the body, probably perform, although in a minor degree, the same function as the angling apparatus

on the head. Although its prey is usually taken at the bottom, it has been known to ascend and float upon the surface of the water in search of food, and thus sometimes to capture sea fowl. Not unfrequently, also, it lays hold on eel or other fish as these are being drawn up hooked to the fisherman's line, and when caught with other fishes in the net it busies itself in devouring as many as possible of its fellow-prisoners. As a food fish the sea devil is valueless, but as the process of its digestion proceeds but slowly, the fishermen often capture it for the fish contained in its stomach. Conch tells of one which, when opened, contained nearly three-fourths of a hundred of herrings, all of them fit for the market. It attains a length of 5 feet, ordinary specimens measuring about 3½ feet. It is an inhabitant of the seas of the temperate regions of Europe, North America, Asia, and Africa.

DEVISE. See WILL.

DEVIZES, a municipal and parliamentary borough and market town of England, in North Wilts, situated on the Kennet and Avon canal, 86 miles west of London by rail. It stands on a plateau in the centre of the county, near the northern limit of Salisbury Plain. The town, which is of considerable antiquity, consists of a market-place with streets diverging therefrom. Some of the houses retain their antique timber construction. In the middle of the market-place there stands a large cross erected by Lord Sidmouth in 1815. The principal public buildings are the town hall, the corn exchange (a spacious and handsome building), the county jail, the Bear Club charity school, and the churches. St John's Church dates from the reign of Henry I., but has received numerous additions and repairs, and was restored in 1863; it belongs to the Norman Perpendicular style of architecture. The building is complete, with nave, transept, chancel, and chantry chapels. St Mary's is also of ancient origin, but was mostly rebuilt in the 15th century. Besides these there are chapels belonging to the various nonconformist bodies. Devizes at one time was famous for its woollen manufactures, but these have long been discontinued, and the only articles now manufactured are silk and stuff. Ale is also brewed. There is, however, a large trade in grain carried on; and the Devizes corn-market is one of the most important in the west of England. The town is said to have taken its rise after the erection of the formidable castle which once stood there, but has now entirely disappeared. This fortress was built about the year 1132 by Bishop Roger of Salisbury, in the reign of Henry I. In 1138 it was seized by Stephen in his campaign against the bishops, and three years thereafter was taken and held by Robert Fitz Herbert on behalf of Queen Maud. He did not, however, retain possession of it for any length of time. It was eventually dismantled in 1376. During the wars of the commonwealth Devizes was unsuccessfully besieged by Waller in 1643, but was taken by Fairfax and Cromwell two years later. It received its borough charter from Maud under the name of *De Vies*; and it is governed by a mayor, 6 aldermen, and 18 councillors. From the time of Edward III. it was represented in Parliament by two members, but the Reform Act of 1868 reduced its representation to one member. The borough, which has an area of 907 acres, is divided into two wards—north and south. Population in 1851, 6554, and in 1871, 6829.

DEVONPORT, a municipal and parliamentary borough of England, in the county of Devon, contiguous to the towns of East Stonehouse and Plymouth, the seat of one of the royal dockyards, and an important naval and military station. It is situated immediately above Plymouth Sound, occupying a triangular peninsula formed by Stonehouse Pool on the east and the Humaze on the west. The town proper is inclosed by a line of ramparts 12 feet

high, protected by a ditch of about 15 feet in depth, excavated out of the solid limestone. Three gates—the Stonehouse gate, the Stoke barrier, and the North barrier—afford communication respectively with East Stonehouse, Stoke, and Morice Town, the last two being suburbs of Devonport. The streets are laid out with regularity, and are paved with a peculiarly white limestone that gives an air of great cleanliness to the town. A copious supply of water is provided by means of a conduit from Dartmoor. The public buildings are both handsome and numerous. The town hall, erected in 1821–22 partly after the design of the Parthenon, is distinguished by an elegant Doric portico, while near it are the public library, in the Egyptian style of architecture, and a conspicuous column or Doric pillar built of Devonshire granite. This monument, which is 100 feet high, was raised in commemoration of the naming of the town in 1824. There are numerous churches belonging to the different religious denominations. Besides the parish church, which is small, several chapels of ease have within the present century been erected in various parts of the town. One of them, a handsome edifice built in 1814–15 at a cost of £24,000, is situated in the dockyards, and was erected for the special use of those employed there. Of the Government buildings the principal are a spacious hospital outside the barriers, the Raglan barracks, and the residences of the military and naval chief officers. On Mount Wise, which is defended by a battery, stands the military residence, or Government house, which is occupied by the commander of the western district, and near at hand is the other residence, the port admiral's house. Mount Wise itself and the parade form interesting features of the place, and tend greatly to the amenity of the town—the prospect from the former being one of the finest in the south of England. The most noteworthy object, however, in connection with Devonport is the royal dockyard, which extends along the shore of the Hamoaze from Mutton Cove to Keyham Lake, a distance of about $1\frac{1}{4}$ miles. The naval dockyard, which formed the nucleus of the town, is situated within the ramparts, and covers an area of 75 acres, with a wharfage of 1160 yards; while beyond the ramparts, and higher up the Hamoaze, is the more recently constructed Keyham steam yard, connected with the former by means of a tunnel 900 yards long. Keyham steam yard occupies an area of 100 acres; and its docks are built of granite. In connection with the dockyards are the gun wharf, and extensive store-houses and factories. The number of hands employed in the works is very large, varying from 3000 to 4000, according to circumstances; and it may be said that, with the exception of a brewery in the suburb of Morice Town, the only manufactory of the place is that belonging to the Government. The history of Devonport is of comparatively recent date. After the outbreak of war with France in 1689 William III. established an arsenal there in connection with the neighbouring naval station of Plymouth, and it received the name of Plymouth Dock. Its proportions were, however, somewhat limited until in 1761 and in 1771 extensive additions were made, and since then it has steadily increased in importance. In 1824 it received its present distinctive name, and by the Reform Act of 1832 it was erected into an independent borough returning 2 members to Parliament. The municipal borough, which is co-extensive with the parish of Stoke-Damerel, is subdivided into 6 wards, and covers an area of 1760 acres, while the area of the parliamentary borough, which includes East Stonehouse, extends to 1950 acres. The town is governed by a mayor, 12 aldermen, and 35 councillors, and has a separate commission of the peace. The ground on which Devonport stands is for the most part the property of the St Aubyn family, whose steward holds a court leet and a court

baron annually. The population of the municipal borough was, in 1851, 38,180; in 1861, 50,440, and in 1871, 49,449—the males being slightly more numerous than the females. The population of the parliamentary borough in 1871 was 64,034. See **PLYMOUTH AND DOCKYARDS**.

DEVONSHIRE, one of the south-western counties of England, the third in extent in the country, being exceeded only by York and Lincoln. According to the latest survey, it contains 1,594,852 acres—equal to about 2492 square miles. On the N. and N.W. the county is bounded by the Bristol Channel, on the S. by the English Channel, on the W. it adjoins Cornwall, on the E. Dorset and Somerset. In form, Devonshire is very irregular, but it sends out one long promontory towards the S., and on the N. the coast line trends sharply southward near Ilfracombe, and is broken into the deep hollow of Bideford Bay.

General aspect—Nearly the whole area of Devonshire is uneven and hilly. It contains the highest land in England, south of the Yorkshire Ingleborough, and the scenery, much varied, is in most parts of the county very striking and picturesque. The great feature of Devonshire is the granitic district of Dartmoor, so named from the principal river which rises on it, the Dart, and occupying an area of about 130,000 acres. This great plateau, the mean height of which is about 1500 feet, rises in the southern division of the county, and is more or less conspicuous from all the lower tracts. It is the highest and easternmost in a broken chain of granite elevations, which extends to the Scilly Islands. Steep heights, crested with masses of broken granite, locally named *tors*, break up from the main table land in all directions, and are often singularly fantastic in outline. The highest of these is Yestor, 2050 feet, in the northern quarter; whilst one of the most conspicuous is Heytor, 1501 feet, in the south. Dartmoor is a region of heather, and the central portion has been a royal forest from a period before the Conquest. Its grand wastes contrast finely with the wild but wooded region which immediately surrounds the granite (and along which occurs the most picturesque scenery in Devonshire), and with the rich cultivated country lying beyond. It is this rich country which has given Devonshire the name of the Garden of England. The most noticeable districts are the so-called Vale of Exeter, covering an area of about 200 square miles, and including the meadows which surround Crediton, the richest in the county; and the South Hams, the extent of which is not very clearly defined, but which covers the deep projection between the mouths of the Dart and the Erme. Another very picturesque division extends eastward of Exeter as far as the Dorsetshire border. The north and south coasts of the county differ much in character and climate, the north being by far the more bracing. Both have grand cliff and rock scenery, not exceeded by any in England or Wales; and, as a rule, the country immediately inland is of great beauty. The general verdure of Devonshire, and its broken hilly character, are the features which everywhere most strongly assert themselves. The least picturesque part of the country is that toward the centre, which is occupied by some portions of the Carboniferous formation.

The principal rivers rise on Dartmoor, and are—the Teign, the Dart, the Plym, and the Tavy, falling into the English Channel, and the Taw and the Torridge, flowing north towards Bideford bay. The lesser Dartmoor streams are the Avon, the Erme, and the Yealm, all running south. The Exe rises on Exmoor in Somersetshire, but the main part of its course is through Devonshire (where it gives name to Exeter), and it is joined on its way to the English channel by the lesser streams of the Culm, the Creedy, and the Glyn. The Otter, rising on the Blackdown hills, also runs S., and the Axe, for part of its course, divides the

counties of Devon and Dorset. These eastern streams are comparatively slow and still-flowing. The Dartmoor rivers, rapid, dashing, and rocky, are famous trout streams. None have courses of any great length.

The *geological formations* of Devonshire are of course the main cause of the general appearance of the county. Dartmoor, as has been said, is a granite region. By far the greater part of central Devon is occupied by Carboniferous rocks, consisting chiefly of sandstones, often siliceous, and of slates. All this formation has been subjected to great disturbances, and the strata (as may be seen on every part of the coast between Bosccastle and the mouth of the Taw), are twisted in a manner which defies description, the result being some very extraordinary and picturesque cliff scenery. True coal does not exist, but anthracite occurs near Bideford. These rocks are also associated with trappean and other ashes, which bear a striking analogy to those of existing volcanoes. Underlying the carbonaceous deposits are the grauwacke or Devonian rocks, forming the extreme north of the county, and great part of the South Hams. They extend west of Plymouth, and cover the greater part of Cornwall. These rocks are generally held to be the equivalents of the "Old Red" system, although the characteristic Old Red rocks, so largely developed in Scotland, Herefordshire, and elsewhere, are not found at all in Devonshire. The Devonian rocks consist of clay-slates, grey limestones, brown sandstones, and flags. The fossils of the two series also differ, but although these Devonians offer many complexities, this and other differences seem capable of explanation. The third great formation of Devonshire is the New Red, which occupies much of the eastern portion of the county, extends along the coast from Sidmouth to Torbay, and sends out a long spur westward into the Carboniferous district. The upper beds of the series consist principally of marls, the middle of sandstones, and the lower of breccias or coarse conglomerates, coloured red by peroxide of iron. The formation is characterized by a scarcity of organic remains, and by the extreme fertility of some of its soils.

At or near the junction of the Carboniferous and New Red formations, from Washfield, near Tiverton, on the N. to Haldon on the S, occur numerous masses of igneous rock, feldspathic traps. These traps are for the most part excellent building stones, and many of the quarries have been worked for ages. Greenstones and elvans are also associated with the Devonian series. Greensand strata cap the Blackdown hills, and the heights near Axminster, Seaton, and Sidmouth, and with beds of chalk, occupy a depression in the coast at Beer (near the eastern border of Devonshire), coming down to the level of the sea at Beer Head. A very interesting and remarkable Tertiary deposit, belonging to the Lower Miocene period, occurs at Bovey Tracy, below the eastern escarpment of Dartmoor. It consists of beds of lignite, clay, and sand, with an aggregate thickness of more than 100 feet. In the lignites at least 50 species of plants have been found, all indicating a sub-tropical climate; but the greater part of the lignite beds is formed by fragments of an enormous coniferous tree, belonging to the genus *Sequoia*, the only living species of which are to be found in California. Great lumps of inspissated resin occur occasionally. The clay which overlies the lignites is of much more modern date, and contains leaves of the dwarf birch, now an arctic plant, and of 3 species of willow, which all betoken a much colder climate than that of Devonshire at present. Fine potters' clay occurs above this "head" of coarse clay and sand, and has been turned to account. The lignite called "Bovey coal" burns with a disagreeable smell, and is not much used.

The *ossiferous caverns* of Devonshire are famous in

geological history. The most important is Kent's Hole, near Torquay, which has been carefully explored, and appears to have been frequented by bears, hyenas, and, at last, by primitive man. There are others at Brixham, at Chudleigh, and at Oreston near Plymouth.¹

Minerals.—The minerals of most account are tin and copper. Iron occurs, but to no great extent. The *silver-lead* mines at Combe Martin on the N. coast, and at Beer Alston, on the Devonshire side of the Tamar, were formerly worked to advantage; but the former have long been abandoned, and the latter, since 1860, have been swamped by water from the river, under the bed of which the principal mine extended. Tin has been found on Dartmoor (in stream works) from an unknown period. Copper was not much worked before the end of the last century. Tin occurs in the granite of Dartmoor, and along its borders, but rather where the Devonian than where the Carboniferous rocks border the granite. It is found most plentifully in the district which surrounds Tavistock, which, for tin and other ores, is in effect the great mining district of the county. Here, about 4 miles from Tavistock, are the Devon Great Consols mines, which from 1813 to 1871 were among the richest copper mines in the world, and by far the largest and most profitable in the kingdom. The divided profits during this period amounted to £1,192,960. But the mining interests of Devonshire are affected by the same causes, and in the same way, as those of Cornwall. The quantity of ore has greatly diminished, and the cost of raising it from the deep mines prevents competition with foreign markets. In many mines tin underlies the general depth of the copper, and is worked when the latter has been exhausted. The metalliferous character of the Tavistock district is indeed very mixed, and besides tin and copper, ores of zinc and iron are largely distributed, but these have as yet received no great attention. At the Devon Great Consols more than 2000 tons of refined arsenic are annually produced by elimination from the iron pyrites contained in the various lodes. This amount is calculated to be about one-third of the arsenic produced throughout Europe. *Manganese* occurs in the neighbourhood of Exeter, in the valley of the Teign, and in N. Devon; but the most profitable mines, which are shallow, are, like those of tin and copper, in the Tavistock district.

The other mineral productions of the county consist of marbles, building-stones, slates, and potters' clay. *Marbles* occur in the Carboniferous series at Chudleigh and elsewhere, but of very inferior character and beauty to those among the Devonian rocks, at Ipplepen, Babbacombe near Torquay, and Plymouth. These are largely worked, and are used extensively in the decoration of churches and other buildings. Among *building stones*, the granite of Dartmoor holds the foremost place. It is much quarried near Prince Town, near Moreton Hampstead on the N. of Dartmoor, and elsewhere. The annual export is considerable. There are very large and ancient quarries of a chalky greensand at Beer, near the eastern border of the county. This is an excellent building stone, nearly white, and composed of carbonate of lime, mixed with argillaceous and siliceous matter, and with particles of green silicate of iron. Hard traps, which occur in many places, are also much used, as are the limestones of Buckfastleigh and of Plymouth. The Roborough stone, used from an early period in Devonshire churches, is found near Tavistock, and is a hard, porphyritic elvan, taking a fine polish. Excellent *roofing slates* occur in the Devonian series round the S. part of Dartmoor. The chief quarries are near Ashbur-

¹ For a full account of the literature connected with the caverns, and of the discoveries made in them, see *Transactions of the Devonshire Association*, and the annual reports, by Mr W. Pengelly, of the committee appointed by the British Association in 1864.

E N G L I S H C H A N N E L

ton and Plymouth (Cann quarry), but none of them are so extensive or important as those at Delabole in Cornwall. *Potters' clay* is worked at King's Toignton, whence it is largely exported, at Bovey Tracy, and at Watcombe near Torquay. The Watcombe clay is of the finest quality, and is capable of retaining the most delicate form. *China clay* or kaolin, is found on the S. side of Dartmoor, at Lee Moor, and near Trowlesworthy. There is a very large deposit of *umber*, as yet little known, close to Ashburton.

Climate.—The climate varies greatly in different parts of the county but everywhere it is more humid than that of the eastern or south-eastern parts of England. Both Devon and Cornwall have a mean annual temperature about 1°·5 above that of the midland counties; but in the summer they are cooler than the whole range of country from the south coast to the 53° of lat. The air of the Dartmoor highlands is sharp and bracing. Mists are frequent, and snow often lies long. On the south coast frost is little known, and many half hardy plants, such as hydrangeas, myrtles, geraniums, and heliotropes, live through the winter without protection. The climate of Sidmouth, Teignmouth, Torquay, and other watering places on this coast, is very equable, and the mean temperature of the winter months is about 47°. The N. coast, exposed to the storms and swell of the Atlantic, is far more bracing; although there also, in the more sheltered nooks (as at Combe Martin), myrtles of great size and ago flower freely, and produce their annual crop of berries.

Agriculture.—While the eastern division of England, ranging from Yorkshire to Hampshire and Sussex, is essentially a corn-growing country, the south-western is as specially the grazing or pasture-land division. The total amount of land in Devonshire under corn crops in 1876 was 283,332 acres, of which 112,652 were under wheat, 152,370 under green crops, 189,761 under clover, saufoin, and grasses under rotation, and the permanent unbroken pasture (exclusive of the moors) extended to 442,406 acres. Of horses used solely for agricultural purposes, the number returned in 1876 was 51,753, of cattle, 217,111; of sheep, 943,542, of pigs, 90,773. These numbers, as compared with those of former years, show a steady progress, and an annual increase in the extent of permanent pasture. In the small farms on Dartmoor and along its borders grain crops are very uncertain, and on Dartmoor itself even oats do not ripen in unfavourable seasons. The root and other crops obtained on the land attached to the convict prison are due to the amount of manual labour expended on them, which in ordinary cases would be altogether without profit. Devonshire is one of the cider-producing counties of England, soil and climate being favourable to the growth and bearing of the apple. The acreage of Devonshire orchards in 1876 was 24,097. The two other principal cider counties had respectively—Hereford, 24,616 acres planted with fruit trees (apples and pears), and Somerset, 21,029.

As respects the ownership of the land, according to the Owners of Land Return for 1873, the county was divided among 31,809 proprietors, whose aggregate estimated rental amounted to £2,881,665. Of that number 21,647 or 68 per cent. owned less than 1 acre—the proportion of small proprietors in all England being 71 per cent.; and the rental per acre averaged £1, 18s 0d, as against £3, 0s 2d in all England. Nearly one fifth of the land was owned by 15 proprietors:—To the Duchy of Cornwall belonged 48,457 acres; Hon. Mark Rolle, Stevenstone, Torrington, 45,088; Duke of Bedford, 22,607; Earl of Devon, Powderham Castle, 20,588; Earl Fortescue, Castle Hill, 20,171; Lord Poltimore, Court Hall, 17,047; F. W. Knight, Exmoor, 16,903; Earl of Portsmouth, Eggesford House, 16,414; Sir George Stucley, Bart., Hartland

Abbey, 15,144; Sir T. D. Acland, Bart., Killerton, 15,018; Lord Clinton, Heanton Satchville, 14,431; Sir Massey Lopes, Bart., Maristow, 11,977; M. Preston, Chulmleigh, 11,280; Sir W. P. Carew, Bart., Newton Abbot, 10,889, and Sir Lawrence Palk, Bart., Haldon House, 10,109.

Industries.—Devonshire has few manufactures, and no very important industrial works. There is a considerable pottery at Bovey Tracy, manufacturing white, printed, and painted ware; and another at Watcombe, where the productions are finer and more artistic. Blankets and serges are made at Buckfastleigh and at Ashburton, and the factories employ many hands. At Tiverton there is an extensive lace-making factory. The manufacture of Honiton lace, made by hand on the pillow, is now confined to Beer and some other villages on the S.E. coast. Shoes and boots, chiefly for export, are made at Crediton. The greatest industrial works in the county however, are the vast Government establishments at Plymouth and Devonport—the victualling yard, and the dockyard. The convict prisons in Dartmoor may also be regarded as an industrial establishment. They were built for French prisoners in 1809, and in 1850 were adapted for receiving convicts. Since that year more than 100 acres round the prisons have been brought into cultivation under convict labour, and 1000 acres more were added to the prison lands in 1871. In addition to the old buildings, a large prison, arranged on the latest principles, was erected in 1872.

The fisheries of Devonshire are in no way so important as those of Cornwall. About 200 trawlers belong to the port of Brixham, the head quarters of the fisheries of Tor Bay. Herrings and mackerel visit the coasts in their seasons, but not in the vast shoals known farther west. It may be said that trawling is the main feature of the Devonshire fishery whilst seining and draving characterize that of Cornwall.

History.—The British tribes inhabiting this western portion of the island are called *Dumnonii* by Ptolemy, and *Dumnonia*, or *Dammonia*, the Latinized name of a kingdom which long remained independent after the arrival and early conquests of the West Saxons, seems to be identical with the Cymric *Dyfnaint*, which survives in the present Devon. The Saxon settlers, as they advanced into the country, called themselves *Defenas*, i.e., men of Devon or *Dyfnaint*, thus adopting the British name, and indicating the broad difference between their settlements in such a district as Devon, where British influence so long survived, and where they came as Christians, and those in southern or eastern England, where the Britons were either expelled or exterminated. In Devonshire the Christian Britons became subjects of the Christian Saxons. "The Celtic element can be traced from the Somersetshire Axe, the last heathen frontier, to the extremities of Cornwall, of course increasing in amount as we reach the lands which were more recently conquered, and therefore less perfectly Teutonized. Devonshire is less Celtic than Cornwall, and Somersetshire is less Celtic than Devonshire; but not one of the three counties can be called a pure Teutonic land, like Kent or Norfolk" (E. A. Freeman). Celtic names are accordingly found in various parts of Devonshire, and especially on Dartmoor, side by side with those which are truly Saxon.

For some time after the landing of William I. and the battle of Hastings, the western counties remained undisturbed. In the spring of 1068 Exeter was besieged and taken by the Conqueror, who built a castle there, which was besieged in 1137 by Stephen for three months. In 1469 Exeter, which was Lancastrian, was besieged for twelve days by the Yorkists, but held out successfully; and in 1497 the city was again besieged by Perkin Warbeck. A more

important siege occurred in 1549, when the western counties rose in defence of what was called the "old religion." This lasted for 35 days. Both Exeter and Plymouth were besieged for many months during the civil war of the Commonwealth. This was a period of considerable disturbance in the west. The golden age of Devonshire is, however, that of Elizabeth. Drake, Hawkins, Raleigh, and the Gilberts, besides a host of others, were all of Devonshire; and the history of the county at that time is bound up with the story of its harbours and seaside towns, and is in close connection with the general history of England. It was from Plymouth that the English ships sailed for the attack and dispersal of the Armada, the near approach of which was there first made certain. The landing of William of Orange at Brixham, November 5, 1688, is perhaps the event most fraught with important results which has taken place in the western counties.

Antiquities.—In primeval antiquities Devonshire is not so rich as Cornwall, but Dartmoor abounds in remains of the highest interest, the most peculiar of which are the long parallel alignments of upright stones, which, on a small scale, resemble those of Carnac in Brittany. On Dartmoor the lines are invariably straight, and are found in direct connection with cairns, and with circles which are probably sepulchral. These stone avenues are very numerous. Of the so-called sacred circles the best examples are the "Longstones" on Scorchill down, and the "Grey Wethers" under Sittaford tor. By far the finest cromlech is the "Spinster's Rock" at Drewsteignton, a three-pillared cromlech which may well be compared with those of Cornwall. There are numerous menhirs or single upright stones; a large dolmen or holed stone lies in the bed of the Teign, near the Scorchill circle, and rock basins occur on the summit of nearly every tor on Dartmoor (the largest are on Kestor, and on Heltor, above the Teign). It is, however, tolerably evident that these have been produced by the gradual disintegration of the granite, and that the dolmen in the Teign is due to the action of the river. Clusters of hut foundations, circular, and formed of rude granite blocks, are frequent, the best example of such a primitive village is at Batworthy, near Chagford, the type resembles that of East Cornwall. Walled inclosures, or ponds, occur in many places, Grimspound is the most remarkable. Trackways, or boundary lines, run across Dartmoor in many directions; and the rude bridges, formed of great slabs of granite, deserve notice. All these remains are on Dartmoor. Scattered over the county are numerous large hill castles and camps,—all earthworks, and all apparently of the British period. Roman relics have been found from time to time at Exeter (*Isca Damnoniorum*), the only large Roman station in the county.

Buildings.—The churches are for the most part of the Perpendicular period, dating from the middle of the 14th to the end of the 15th century. Exeter Cathedral is of course an exception, the whole (except the Norman towers) being very beautiful Decorated work. The special features of Devonshire churches, however, are the richly carved pulpits and chancel screens of wood, in which this county exceeded every other in England, with the exception of Norfolk and Suffolk. The designs are rich and varied, and the skill displayed often very great. Granite crosses are frequent, the finest and earliest being that of Coplestone, near Crediton. Monastic remains are scanty; the principal fragments are those at Tor, Buckfast, Tavistock, and Buckland Abbeys. Among domestic buildings the houses of Wear Gifford (15th century), Bradley (15th century), Dartington (15th), Bradfield (Elizabethan), and Holecombe Rogus (Elizabethan) deserve notice. The ruined castles of Okehampton (Edward I.), Exeter (with vast British earthworks), Berry Pomeroy (Henry III., and with ruins of a

large Tudor mansion), Totnes (Henry III.), and Compton (early 15th century), are all interesting and picturesque.

The dialect of Devonshire belongs, of course, to the West Saxon division; but the mixture of dialects here was, as has been said, considerable; and in the language as well as in the folk-lore of the people Celtic words and ideas are found closely united with those of Teutonic origin.

The episcopal see for Devonshire was at first established at Crediton, in 909. The ancient Cornish see, which had existed during the British independence of Cornwall, was afterwards united to that of Crediton, and in 1050 the place of the united sees was removed by the Confessor from Crediton to Exeter. There was no further change until 1876, when the Cornish see was again separated from that of Devonshire, and the place of it fixed at Truro. The diocese of Exeter is now therefore confined to Devonshire.

Devonshire is in the western circuit, and the assizes are held at Exeter. It has one court of quarter sessions and 22 petty sessional divisions. The city of Exeter, a county of itself, and the boroughs of Barnstaple, Bideford, Dartmouth, Devonport, Plymouth, South Molton, Tiverton, and Totnes have commissions of the peace, and, with the exception of Totnes, separate courts of quarter sessions. The jurisdiction of the court of the vice-warden of the stannaries extends over the county of Devon as well as that of Cornwall. There are 23 lieutenant subdivisions. For the purposes of parliamentary election, Devonshire is divided into east, north, and south—each of which divisions returns 2 county members. The city of Exeter, in East Devon, returns 2; Barnstaple and Tiverton, in North Devon, 2 each; Devonport and Plymouth, in South Devon, 2 each, and Tavistock, also in South Devon, returns 1 member. There are thus altogether 17 members returned for Devonshire.

One of the earliest railways in England was that from Plymouth to the prisons at Prince Town on Dartmoor, opened in 1825. It was, and is, used only by horse cars. The county is now well intersected by railways. Of canals, the most important (and, except "Morton's Leam," running from near Peterborough to the sea, the most ancient in England) is the Exeter Ship canal, cut in the reign of Henry VIII., and extended in 1826. It is about six miles in length, and connects the city of Exeter with the mouth of the River Exe. Tiverton is connected with Taunton by the Grand Western canal, 23 miles long; and a canal completed in 1817 connects Tavistock with the Tamar.

The principal gentlemen's seats in Devonshire are Saltram (earl of Morley), Maristow (Sir Massey Lopes, Bart.), Kitley (Baldwin Bastard, Esq.), Stover (duke of Somerset), Ugbrooke (Lord Clifford), Haldon (Sir Lawrence Palk, Bart.), Mannhead (Sir Lidstone Newman, Bart.), Powderham Castle (earl of Devon), Killerton (Sir Thomas Acland, Bart.), Bieton (Lady Rolle), Castle Hill (Earl Fortescue), Tavistock (Sir Bourchier Wrey, Bart.), and Eggesford (earl of Portsmouth). There are many lesser houses noticeable for beauty of situation or for the ornamental grounds in which they stand. Of these by far the most remarkable are Endsleigh (duke of Bedford), near Tavistock, commanding some of the finest scenery in the upper valley of the Tamar, and Buckland Court, on the Dart (Baldwin Bastard Esq.).

The principal towns in the county are those already mentioned as returning members to Parliament, or as possessing courts of quarter sessions. Besides these are the watering-places of Tignmouth, Torquay, and Ilfracombe, and the smaller towns of Crediton, Honiton, Axminster, Ashburton, and Newton Abbot.

Population.—The total population of Devonshire in 1851 amounted to 567,098 persons; in 1861 to 584,373; and in

1871 to 601,374, of whom 285,248 were males, and 316,126 females. There were, at the last census, on an average 0.36 persons to an acre, or 2.75 acres to each person. The number of inhabited houses was 105,200. There were 480 parishes and 33 hundreds. The population of the county in 1801 was 340,308 persons; so that the increase since that time has been at the rate of 77 for every hundred. Of the 52 counties in England and Wales, Devonshire is now the ninth in point of population. The comparative density of the population is considerably below the average. In England generally there are 389 persons to every square mile; in Devonshire the number is not more than 232.

Bibliography—The best general history of the county is still that which forms part of Lysons's *Magna Britannia* (1822). Polwhele's *Hist. of Devon* (1793-98) was never completed, and is inaccurate. Westcote's *Survey of Devon*, written about 1630, and first printed in 1845, is curious and important. Prince's *Worthies of Devon*, a very valuable book, was first published in 1701, and was reprinted in 1810. Oliver's *Monasticon Diocesis Exoniensis* (1845) is valuable for the history of the monastic foundations in both Devon and Cornwall. There are very good histories of Plymouth (1871) and of Devonport (1872) by R. N. Worth. Mrs. Bray's *Borders of the Tamar and Tavy*, 3 vols., 1836, is full and interesting, and contains much information relating to Dartmoor. Rowe's *Perambulation of the Forest of Dartmoor* (1848, and later editions) is still the most complete book on that district, but a great amount of important matter relating to Dartmoor and to the county in general will be found in the annual volumes of the *Transactions of the Devonshire Association for the Promotion of Literature, Science, and Art*, beginning in 1862. The notes to Carrington's poem of *Dartmoor* should also be mentioned.

For the geology of the county reference should be made to the very valuable papers of Mr. Pengelly in the *Transactions of the Devonshire Association*, and in the *Journal of the Geological Society*. The papers of Mr. Ormerod and of Mr. Vicary in the same Journals are also of great importance. The fullest general notice is, however, to be found in the *Report on the Geology of Cornwall, Devon, and West Somerset*, by Sir H. J. De la Beche, 1839. Murray's *Handbook for Travellers in Devon and Cornwall* (8th ed., 1872) must also be mentioned as full of useful information. (R. J. K.)

DEVONSHIRE, WILLIAM CAVENDISH, FOURTH EARL AND FIRST DUKE OF (1640-1707), distinguished as a statesman and patriot, born in 1640, was the eldest son of the third earl. After completing his education he made the tour of Europe according to the custom of young men of his rank, being accompanied on his travels by Dr. Killigrew. On his return he obtained, in 1661, a seat in Parliament for the county of Derby, and soon became conspicuous as one of the most determined and daring opponents of the general policy of the court. In 1678 he was one of the committee appointed to draw up articles of impeachment against the lord-treasurer Danby. In 1679 he was re-elected for Derby, and made a privy councillor by Charles II., but he soon withdrew from the board with his friend Lord Russell, when he found that the Romish interest uniformly prevailed. He carried up to the House of Lords the articles of impeachment against Lord Chief-Justice Scroggs, for his arbitrary and illegal proceedings in the Court of King's Bench; and when the king declared his resolution not to sign the bill for excluding the duke of York, afterwards James II., he moved in the House of Commons that a bill might be brought in for the association of all his majesty's Protestant subjects. He also openly denounced the king's counsellors, and voted for an address to remove them. He appeared in defence of Lord Russell at his trial, at a time when it was scarcely more criminal to be an accomplice than a witness. After the condemnation he gave the utmost possible proof of his attachment by offering to exchange clothes with Lord Russell in the prison, remain in his place, and so allow him to effect his escape. In November 1684 he succeeded to the earldom on the death of his father. He opposed arbitrary government under James II. with the same consistency and high spirit as during the previous reign. He was withdrawn from public life for a time, however, in consequence of a

hasty and imprudent act of which his enemies knew how to avail themselves. Fancying that he had received an insulting look in the presence chamber from Colonel Colepooper, a swaggerer whose attendance at court the king encouraged, he immediately avenged the affront by challenging the colonel, and, on the challenge being refused, striking him with his cane. This offence was punished by a fine of £30,000, which was an enormous sum even to one of the earl's princely fortune. Not being able to pay he was imprisoned in the King's Bench, from which he was released only on signing a bond for the whole amount. This was afterwards cancelled by King William. After his discharge the earl went for a time to Chatsworth, where he occupied himself with architectural improvements on his mansion. The Revolution again brought him into prominence. He was one of the seven who signed the original paper inviting the Prince of Orange from Holland, and was the first nobleman who appeared in arms to receive him at his landing. He received the Order of the Garter on the occasion of the coronation, and was made lord high steward of the new court. In 1691 he accompanied King William on his visit to Holland. He was created marquis of Hartington and duke of Devonshire in 1694 by William and Mary, on the same day on which the head of the house of Russell was created duke of Bedford. Thus, to quote Macanlay, "the two great houses of Russell and Cavendish, which had long been closely connected by friendship and by marriage, by common opinions, common sufferings, and common triumphs, received on the same day the highest honour which it is in the power of the Crown to confer." His last public service was assisting to conclude the union with Scotland, for negotiating which he and his son, the marquis of Hartington, had been appointed among the commissioners by Queen Anne. He died on the 18th August 1707, and ordered the following inscription to be put on his monument.—

Wilhelmus Dux Devon,
Bonorum Principum Fidelis Subditus,
Inimicus et Invidus Tyrannus.

DEW. See METEOROLOGY.

DEWBERRY, *Rubus cerasus*, a deciduous trailing plant, allied to the bramble, of the natural order *Rosaceæ*. It is common in woods, hedges, and the borders of fields in England and other countries of Europe. The leaves are trifoliate, hairy beneath, and of a dusky green, the flowers, which appear in June and July, are white, or pale rose-coloured. The fruit is large, and closely embraced by the calyx, and consists of few grains, which are black, with a glaucous bloom; it has an agreeable acid taste, and is used for making a kind of wine.

D'EWES, SIR SIMONDS (1602-1650), antiquarian, chronicler, and collector of historical records, was born at Coxden, in the parish of Charstock, in Dorsetshire, on the 18th December 1602. His father, one of the six clerks of Chancery, possessed a large official income, and gave him a liberal education at the grammar-school of Bury St Edmunds, and at St John's College, Cambridge. Called to the bar in 1623, he did not enter upon practice, being possessed of independent means, and having already resolved to devote himself to historical research. His intention seems to have been to compile a history of Britain from original documents, and in endeavouring to carry it out he spent much of his time in examining historical records, which he describes as "the most ravishing and satisfying part of human knowledge," in the Tower of London and elsewhere. The chief results of this labour were his valuable collection of records—originals and transcripts—which now form part of the Harleian collection in the British Museum, and his *Journals of all the Parliaments in the reign of Queen Elizabeth*, which, though completed in

1629, was first published by his nephew, Paul Bowes, in 1682. His means had been considerably increased by his marriage with an heiress in 1626, soon after which he procured the honour of knighthood. One of his many foibles was a desire to establish for himself an aristocratic lineage, and his efforts to do this, in spite of the fact he is forced to admit, that he does not know who his great-grandfather was, are very amusing. In 1639 he became high sheriff of Suffolk, and in 1641 he was made a baronet. In the intervening year he entered the Long Parliament as member for Sudbury. Here he obtained a peculiar place for himself by his whimsicality, and his parade of his knowledge of records, which he quoted at first in nearly every debate, sometimes relevantly, but oftener not. He was treated for a time with a sort of amused tolerance, but ultimately his innumerable interferences with the conduct of business had to be checked. He was not a very warm adherent of the cause of the Parliament against the king. Belonging to the Presbyterian section of the Puritan party, he was excluded from the House of Commons by "Pride's Purge" in 1648. He died on the 18th April 1650. The *Autobiography and Correspondence of Sir Simonds D'Ewes*, edited by J. O. Halliwell, was published in 1845, and possesses considerable historical value. Much more important, however, are his manuscript notes of the Long Parliament, describing its sittings between 1640 and 1645 with great graphic power and minuteness of detail. They form five volumes of the Harleian manuscripts in the British Museum, and have been largely drawn upon by John Forster and other writers on the period of the Long Parliament.

DE WETTE, WILHELM MARTIN LUBENICHT (1780-1849), a distinguished German theologian, was born on the 12th January 1780, at Uhl, near Weimar, where his father was clergyman. After receiving his preliminary education at a local school he was sent to the gymnasium at Weimar, a town which was then at the height of its literary glory. Here, as he himself testified in glowing terms many years later, he was much influenced by intercourse with Herder, who as "ephorus" frequently visited the gymnasium and examined the pupils. In 1799 he entered on his theological studies at the university of Jena, his principal teachers being Griesbach and Paulus, from the latter of whom more than any other he derived the tendency to free critical inquiry which characterized him as an expositor. Herder and Paulus were thus in some sense his spiritual fathers, but the relationship was entirely one of spirit and aim, in method and results he occupied an independent and almost solitary position among German theologians. Having taken his doctor's degree, De Wette at once commenced, according to German custom, the career of a "privat-docent" at Jena, which, however, he was not permitted to continue long. In 1807 he became professor of theology at Heidelberg, and in 1810 he was transferred to a similar chair in the newly-founded university of Berlin, from which he was dismissed in 1819 on account of his having written a letter of consolation to the mother of Sand, the murderer of Kotzebue. The letter was defensible, though it drew a distinction between the morality of the deed and of the door which many were not prepared to admit, and a petition in its author's favour was presented by the senate of the university. The king, however, proved inexorable, and a decree was issued not only depriving De Wette of the chair, but banishing him from the Prussian kingdom. He retired for a time to Weimar, where he occupied his enforced leisure in the preparation of his edition of Luther, and in writing the romance *Theodor oder die Weike des Zweiflers* (Berlin, 1822), in which he describes the education of an evangelical pastor. During this period he made his first essay in preaching, and proved himself to be possessed of very popular gifts. An

invitation to a pastoral charge in Brunswick was under his consideration, when the offer in 1822 of the chair of theology in the university of Basel, which had been re-organized four years before, opened up to him a still more congenial sphere. Though his appointment had been strongly opposed by the orthodox party, De Wette soon won for himself a position of great influence both in the university and in the community of Basel. He was early admitted a citizen, and received many proofs of the esteem of his fellow-townsmen; and the university owed much of its recovered strength, particularly in the theological faculty, to his individual efforts. He died on the 16th June 1849, being rector of the university at the time.

De Wette's chief work as a theologian was in the department of biblical criticism and exegesis, though he made valuable contributions to other branches of theology. In fact his range was unusually extensive, and he did much by precept as well as by example to widen the limits of theological culture. He had considerable poetic faculty, and wrote a drama in three acts, entitled *Die Entzuegung* (Berlin, 1823). He had an intelligent interest in art, and devoted much attention to ecclesiastical music and architecture. As a biblical critic he is sometimes classed with the destructive school, but his position was unique, and cannot be accurately defined by merely referring him to a leader or a school. In the work of interpretation he strove to keep himself entirely free from dogmatic propositions, and he was fearless in recognising and grappling with difficulties; but he was prevented by his deeper spirituality from identifying himself with the hard and uncompromising rationalism of Paulus, and on the other hand his unfettered critical method separated him distinctly from the supernaturalist or strictly orthodox school of interpreters. Thus it has happened that each school has classed him with the followers of the other, as he himself predicted would be the case in the preface to his *Christliche Sittenlehre*. His works are generally admitted to be marked by great exegetical skill, unusual power of condensation, and uniform fairness. Accordingly they possess an element of permanent value which is little affected by the progress of criticism. The following is a list of the most important of them:—

Einleitung zur Einleitung in das Alte Testament (2 vols. 1806-7); *Commentar über die Psalmen* (1811), which has passed through several editions, and is still regarded as of high authority; *Lehrbuch der Hebräisch-hebräischen Archäologie* (1811); *Lehrbuch der Theologie* (1815), a work of great importance as showing its author's general theological position; *Lehrbuch der Christlichen Dogmatik* (1813-16); *Christliche Sittenlehre* (1819-21); *Einleitung in das Neue Testament* (1835); *Religion, der Mensch, ihre Erscheinungsform, und ihre Einfluss auf das Leben* (1827); *Die Weisheit des Christlichen Glaubens* (1846), and *Kurzgefasstes exegetisches Handbuch zum Neuen Testament* (1845). De Wette also edited Luther's works.

See Hagenbach in Herzog's *Real-Encyclopädie*, Büchke's *W. M. L. De Wette, zur freundschafter Erinnerung* (1850), and Schenkel's *W. M. L. De Wette und die Bedeutung seiner Theologie für unsere Zeit* (1849).

DE WINTER, JAN WILHELM (1750-1812), Dutch admiral, was born at the Texel in 1750. He entered the navy at the age of twelve, but after twenty-five years of honourable service he had attained no higher rank than that of lieutenant. In 1787 he took part with the Revolutionists, and on the failure of their efforts fled to France. He then entered the French army, and served under Dumouriez and Pichegru in the campaigns of 1792 and 1793. In 1795 he returned to Holland and was appointed rear-admiral. In the following year he attained the rank of vice-admiral, and was named commander of the fleet at the Texel. The most memorable event in his career was the battle of the Texel, fought on the 11th of October 1797, in which after a gallant struggle the Dutch fleet was defeated

and the admiral taken prisoner by the English under Admiral Duncan. De Winter was in a few months liberated by exchange; and his conduct in the battle was declared by a council of investigation to have nobly maintained the honour of the Dutch flag. He held the post of minister-plenipotentiary to the French republic from 1798 to 1802, when he reassumed the command of the Dutch fleet. He was employed in suppressing the piracies of the Tripolitans, and negotiated a treaty of peace with the Government. He enjoyed the confidence of Louis Bonaparte, king of Holland, and afterwards of the emperor Napoleon I. By the former he was created count of Huessen and made commander-in-chief of his armies by sea and land; and by the latter he was named grand officer of the Legion of Honour, inspector-general of the coasts of the North Sea, and in 1811 commander of the Texel fleet. De Winter died at Paris, June 2, 1812, and his remains were buried in the Pantheon at the public expense.

DE WITT, CORNELIUS (1623–1672), brother of the more celebrated John De Witt, was born at Dort in 1623. In 1650 he became burgomaster of his native town, and member of the states of Holland and West Friesland. He was throughout life closely associated with his brother, whose opinions he shared, and whom he supported with great ability and vigour. Of the eight deputies appointed in 1672 to accompany the naval and military commanders, he was the one selected to go with De Ruyter, and in action he displayed remarkable courage, as he had done under similar circumstances in 1667. Compelled by sickness to leave the fleet, he found on his return to Dort that the revocation of the Perpetual Edict had been signed by his fellow magistrates. He was forced in his sick-room to follow their example, but added after his name the initials V.C. (*in conatus*). See next article

DE WITT, JOHN (1625–1672), an illustrious Dutch statesman, was born at Dort in 1625. He was carefully educated, and early displayed remarkable talents. A work entitled *Elementa Linearum Curvarum*, published in 1650, is attributed to him. His father was a member of the States General of Holland and West Friesland, and well known as a bitter opponent of the house of Orange, which had gradually acquired almost regal functions. William II., prince of Orange, died in 1650; and as his son, afterwards William III. of England, was an infant, the Republican party easily won predominance. De Witt was made pensionary of Dort, and in that position so distinguished himself by his eloquence, firmness, and sagacity, that in 1652, although only twenty-seven years of age, he became grand pensionary of Holland. He held this position for about twenty years, during which he controlled the policy of the United Provinces. He inherited his father's intense jealousy of the Orange family, and steadily laboured to prevent it from ever again rising to power. When he became grand pensionary the United Provinces were at war with England. He had always disapproved of this conflict, and in 1654 succeeded in bringing about peace, conceding to Cromwell his demands with respect to the honours due to the English flag. The treaty included a secret article providing that no member of the house of Orange should in future be elected stadtholder or grand admiral. De Witt was afterwards accused of having suggested this condition to Cromwell; but the latter was also opposed to the claims of a family which was nearly allied to the Stuarts.

After the restoration of Charles II., who had been exposed to many affronts during his residence in Holland, De Witt cultivated the friendship of France; and in 1661 a treaty was concluded by which that country and the United Provinces granted to each other freedom of commerce in their respective ports.—the Dutch guarantee-

ing to the French the possession of Dunkirk, and the French guaranteeing to the Dutch the right of fishing off the coasts of Great Britain and Ireland. The latter provision caused much irritation in England; and it was increased by the incessant quarrels of English and Dutch merchants on the Guinea Coast, each desiring to have a monopoly in the trade of slaves and gold dust. War was declared in 1665, and in a battle off Lowestoft the Dutch fleet was defeated, the remnant taking shelter in the Texel. Antwerp was the only port at which it could be refitted, and the most experienced pilots decided that it was impossible the vessels could be removed thither. De Witt himself, however, with splendid courage, undertook the task, and not only accomplished it, but in a very short time had the fleet once more ready for action. After two more battles, in which the Dutch well sustained their fame for skill and bravery, De Witt entered upon negotiations which resulted in the Peace of Breda in 1667.

Meanwhile, by dint of severe labour, he introduced order into the financial system of the country; and in 1667 the chief object of his life seemed to be attained, for owing to his efforts a Perpetual Edict was passed proclaiming the office of stadtholder for ever abolished. At this time, however, a great danger threatened the Republic. In 1667 Louis XIV. invaded the Spanish Netherlands; and it was clear that if the war ended in the annexation of that country to France it would be difficult to maintain the independence of the United Provinces. De Witt made secret but rapid preparations for resistance, and appealed to England to support Holland in curbing French ambition. Notwithstanding the prejudices of Charles II., Sir William Temple was sent to propose an alliance between England, Holland, and Sweden. De Witt entered so heartily into this scheme that in the spring of 1668 the Triple Alliance was concluded. Louis XIV. saw that for the time his plans were foiled, and with as good a grace as possible signed the Peace of Aix-la-Chapelle. At heart, however, he bitterly resented the course which the States General, guided by De Witt, had taken, and slowly prepared for revenge. By artful diplomacy England and Sweden were detached from the alliance, and several German princes were persuaded to promise that they would join France in an attack on Holland in order to restore certain towns which, it was pretended, properly belonged to the empire.

While Louis was maturing his plans the power of De Witt was being steadily undermined. The Calvinist clergy, who had always been his enemies, excited their congregations against him and his party; and, as the Prince of Orange approached manhood, the people recalled the obligations of the country to his ancestors, and freely expressed doubts whether his rule would not be preferable to that of nobles and wealthy burgesses. The state of public feeling rendered it impossible for De Witt to make ready for the approaching peril. When, therefore, France, England, and the German allies of France proclaimed war against the United Provinces in 1672, and it was found that no effectual resistance could be offered to their attack, popular indignation turned against the grand pensionary. The Prince of Orange was appointed captain and admiral general; and De Witt could only secure that a council of eight deputies of the States General should be associated with the military and naval commanders, one to go with De Ruyter, the other seven with Prince William. This plan added to the confusion, and in a few months after the declaration of war a large part of the country was overrun, and the French were within five leagues of Amsterdam. To save themselves the humiliation of surrender, the towns of Holland and Brabant broke the dykes and laid the surrounding land under water.

The Orange party so profited by these disasters that the Perpetual Edict was revoked, and Prince William assumed the office of stadtholder. De Witt's policy was thus finally defeated, and he himself became an object of general and intense hatred. All sorts of monstrous charges were brought against him, and believed; and his brother Cornelius was falsely accused of conspiring against the life of the stadtholder. Brought to the Hague, Cornelius was there, on July 24, 1672, tortured and condemned to perpetual banishment. In the same town De Witt was assaulted by a band of assassins, who left him lying on the ground under the impression that he was dead. Summoned by a pretended message from Cornelius, De Witt went to visit him in prison, when a mob assembled and murdered the brothers amid circumstances of revolting cruelty.

De Witt is one of the greatest figures of Dutch history. His action in connection with the Triple Alliance proves that he thoroughly understood the central tendencies of European politics, and, whether he is to be praised or blamed for his life-long opposition to the house of Orange, there can be no doubt as to the greatness and purity of his motives. As an administrator he displayed extraordinary energy and resource; and personally he was a man of steady, upright character, loyal and fearless. His *Memoirs* were published at the Hague in 1667; and in 1725, at Amsterdam, appeared *Lettres et Négociations entre Jean De Witt et les Plénipotentiaires des Provinces Unies aux Cours de France, &c., depuis l'an 1652 jusqu'à 1669*. A Life of the two brothers, by Madame Zontclande, was published at Utrecht in 1709.

DEWSBURY, a market-town in the West Riding of Yorkshire, situated at the foot of a hill, on the left bank of the Calder, eight miles S. by W. of Leeds, on the Manchester and Leeds railway. The chief industries are the making of blankets, carpets, druggets, and worsted yarn. A mile from the town is Batley, the centre of the shoddy manufacture. Coal is worked in the neighbourhood of Dewsbury. The parish church of All Saints was for the most part rebuilt in the latter half of the 18th century; the portions still preserved of the original structure are of great antiquity. Paulinus, first archbishop of York, about the year 627 preached in the district of Dewsbury, where Edwin, king of Northumbria, whom he converted to Christianity, had a royal mansion. Dewsbury is said to have been originally called *Duisburgh*, or the town of *Dut*, the tutelary god of the Brigantes. At Kirkless, in the parish of Dewsbury, is the tomb of Robin Hood. The population of the municipal borough of Dewsbury in 1851 was 14,019, in 1871 it was 24,764, while that of the parliamentary borough, which has an extended area, was 54,940. The municipal charter of the town was granted in 1862. It returns one member to Parliament.

DEXTRIN, or starch by the action of dilute acids, alkalis, and diastase or malt extract, and by roasting it at a temperature between 140° and 160° C. (284°–320° Fahr.) till it is of a light brown colour, and smells like over-baked bread. Its name has reference to its powerful dextro-rotatory action on polarized light. The purest dextrin is prepared by boiling 25 parts of sulphuric acid with 125 of starch and adding by degrees a mixture of 100 parts of starch and 125 of cold water. The liquid is then lowered in temperature to 60° or 70° C. (140°–158° Fahr.), at which it is kept for some time; it is next neutralized with chalk, filtered, and evaporated. Dextrin is an uncrystallizable, insipid, odourless, yellowish-white, translucent substance, brittle and friable when thoroughly dried. It dissolves in water and dilute alcohol; by strong alcohol it is precipitated from its solutions as the hydrated compound,

$C_6H_{10}O_5 \cdot H_2O$. Unlike starch it is not coloured blue by iodine. Diastase converts it eventually into maltose, $C_{12}H_{22}O_{11}$; and by boiling with dilute acids and alkalies it is transformed into dextrose, or ordinary glucose, $C_6H_{12}O_6$. It does not ferment in contact with yeast, and in the pure state has probably no reducing action on an alkaline copper solution. If heated with strong nitric acid it gives oxalic, and not mucic acid. Lamprecht has shown that dextrin is present in the flesh-juice of the horse. Dextrin much resembles gum arabic, instead of which it is generally substituted for a great variety of purposes. It is employed for sizing paper, for stiffening cotton goods, and for thickening colours in calico printing, also in the making of lozenges, adhesive stamps and labels, and surgical bandages. In most technical operations the crude solution only is used.

DHAR, a small native state of Malwá, in Central India, under the political superintendence of the British Government. Area, 2500 square miles; population, 150,000 souls. The state contains much fertile ground, the principal agricultural products being wheat, opium, gram, sugar-cane, Indian corn, and cotton. The Rájá is a Puar or Pramár Rájput, who claims descent from the famous King Vikramáditya; but the family only received possession of Dhar in 1749, by gift from the Marhattá Peshwá, Bájí Ráo. Towards the close of the last, and in the early part of the present century, the state was subject to a series of spoliation by Sindhia and Holkar, and was only preserved from destruction by the talents and courage of the adoptive mother of the fifth Rájá. By a treaty in 1819, Dhar passed under British protection, and bound itself to act in subordinate co-operation. The state was confiscated for rebellion in 1857, but subsequently restored to Rájá Anand Ráo Puar, then a minor, with the exception of the detached district of Bairusia, which was granted to the Begam of Bhopál. The revenue of the state is estimated at £80,000 per annum, inclusive of *jagirs*. The military force consists of 276 cavalry, with 800 infantry (including police), 2 guns, and 21 artillery. Road-making is being pushed on. Fifteen schools were attended in 1874 by 350 scholars. Two charitable dispensaries afford gratuitous medical relief. The town of Dhar, situated on the road from Man (Mhow) to Baroda, extends 3½ miles in length by half a mile in breadth, and is surrounded by a mud wall. The fort, built of red stone, forms a conspicuous object outside the city, and contains the Rájá's palace. DHARWAR, a district of British India in the presidency of Bombay, situated between 14° 6' and 15° 53' N. lat., and 74° 50' and 75° 58' E. long. It contains a total area of 4535 square miles, and a population of 988,037 inhabitants. The district is about 116 miles long, with an average width of 77 miles. It is bounded on the N. by the Belgaum and Kaládgi districts, on the E. by the Nizám's territory and Bellári district, on the S. by Mysore, and on the W. by Belgaum and North Kanara districts. The western portions of the district, in the neighbourhood of the Sabyádri range, are rugged and hilly; but towards the east, the land falls away into plains of black soil in many parts very fertile and well suited to the growth of cotton. The chief rivers are the Malprabhá on the north and the Tungbhadrá on the south. The hills are principally composed of hornblende and chloritic schists, gneiss, and mica slate, large interstratified beds of siliceous and ferruginous schists (as at and near Dhárwár) often forming their ridges. Seams and beds of a crystalline white marble occur, which near their junction with the hornblende slate, are often coloured green. Gold is found sparingly in the Dumbal hills, and chick mulgund, and also iron pyrites. Iron ore is worked to a small extent at Tegur, where there was once

a considerable trade in native iron. The most influential classes of the community are Brahmans and Lingayats. The Lingayats number 380,919, or 44 per cent. of the Hindu population; they worship the symbol of Siva, and males and females both carry this emblem about their person in a silver case. The manufactures of the district are not numerous, they consist of cotton and silk cloth, glass bracelets, and articles of ironware. In four towns of the district cotton and mixed silk and cotton fabrics, for male and female attire, are delicately and lastfully woven. Agriculture is the chief industry of the district, the principal products being cotton, exotic and native *jawári*, molasses, and oil of various kinds. Of a total of 1,662,040 acres of Government arable and assessed land, 1,530,235 acres were in 1874 under cultivation as follows:—Rice, 90,896 acres; cotton, 283,810; *jawári*, 497,312; *báji*, 6126; wheat, 112,169; sugar-cane, 2909; tobacco, 790; *til* seed, 29,647; linseed, 7966; gram, 23,411; miscellaneous products, 294,491; fallow land, 182,869 acres. The cotton trade of Dhárwar has great commercial importance. The land revenue realized in 1875 amounted to £196,064. The district contains six municipalities.

The territory comprised within the district appears at the earliest recorded period to have formed part of the Brahmanical realm of Vijayanagar. On the overthrow of its king at Talikot in 1565, the lands of Dhárwar became part of the Mussulman kingdom of Bijápur. In 1675 the district seems to have been overrun and partially conquered by Suráji, becoming thereby subject to the king of Satára, and subsequently to the Peshwá. In 1776 the province was overrun by Hyder Ali, the usurping sultan of Mysore. In 1778 Dhárwar was taken from the Marhattás by Hyder Ali, and in 1791 retaken by a British force. On the final overthrow of the Peshwá in 1818, Dhárwar was incorporated with the territory of the East India Company.

DHOLPUR, a native state of Rájputáná, in Upper India, under the political superintendence of the British Government, is situated between 26° 30' and 26° 57' N. lat., and 77° 32' and 78° 20' E. long. The state is bounded on the N. and N.E. by the British district of Agra, on the E. and S. by the Gwalior state, from which it is separated by the Chambal river, and on the W. by the state of Karauli. It contains an area of about 1600 square miles, and an estimated population of upwards of 500,000 souls. It is a crop-producing country, without any special manufactures. All along the bank of the Chambal the country is deeply intersected by ravines; low ranges of hills in the western portion of the state supply inexhaustible quarries of fine-grained and easily-worked red sandstone. The chief, who has the title of Ráná, belongs, like most of his subjects, to the tribe of Deswáli-Játs, who are believed to have formed a portion of the Indo-Seythian wave of invasion which swept over Northern India about 100 A.D. The earliest recorded ancestor of the family is one Jeyt Singh, who in 1068 held certain territories south of Alwar. His descendant in 1505, Singan Deo, having distinguished himself in an expedition against the freebooters of the Deccan, was rewarded by the sovereignty of the small territory of Gohad, with the title of Ráná. The family gradually extended their possessions until they included 56 estates, yielding an annual revenue said to amount to 66 lakhs of rupees (£660,000). Upon the defeat of the Marhattás at Panipat in 1761, Ráná Bhim Singh, the tenth in descent from Ráná Singan Deo, seized upon the fortress of Gwalior. Political relations between the Ráná and the East India Company commenced in 1779 during the Marhattá war, when an offensive and defensive alliance was entered into. The Ráná joined the British forces against Sindhua, on receiving a promise that, at the

conclusion of peace between the English and the Marhattás, all the territories then in his possession should be guaranteed to him, and protected from invasion by Sindhua. This protection was subsequently withdrawn, the Ráná having been guilty of treachery. In 1783, Madhoji Sindhi succeeded in recapturing the fortress of Gwalior, and crushed his Ját opponent by seizing the whole of Gohad. In 1803, however, the family were restored to their ancestral possessions of Gohad by the British Government, but, owing to the opposition of Sindhua, the Ráná agreed to relinquish possession of Gohad, in exchange for his present territory of Dholpur. By the treaty of 1804, the state was taken under the protection of the British Government,—the chief becoming bound to act in subordinate co-operation with the paramount power, and to refer all disputes with neighbouring princes to the British Government. The annual revenue of Dholpur, including *jagirs*, amounts to about £110,000. The military force consists of 2000 men. The town of Dholpur is situated on the Agra and Gwalior road.

DIABETES (from *diá*, through, and *baíno*, to pass), a disease characterized by a habitually excessive discharge of urine. Two forms of this complaint are described, viz.—Diabetes Mellitus, or Glycosuria, where the urine is not only increased in quantity, but also contains a greater or less amount of sugar, and Diabetes Insipidus, or Polyuria, where the urine is simply increased in quantity, and contains no abnormal ingredient. The former of these is the disease to which the term diabetes is most commonly applied, and is by far the more serious and important ailment.

Although sometimes classed by medical writers among diseases of the kidneys, *diabetes mellitus* is rather to be regarded as a constitutional disorder. Its cause is still a matter of uncertainty, but there is sufficient evidence to connect it with a defect in the process of the assimilation of food, more especially that stage in which the function of the liver is concerned. The important researches of Claude Bernard, and subsequently those of Schiff, Harley, Pavy, M'Donell, and others, have shown that this organ, besides the secretion of bile, has the additional function of forming in large quantity a substance to which the names of glycogen, dextrin, or amyloid substance have been given. This matter is capable of being converted by the action of ferments into glucose, or grape sugar, and such a change is supposed by some to take place normally in the blood where the sugar thus formed is consumed by oxidation in the course of the circulation, while by other authorities it is held that the glycogen is not directly converted into sugar, but is transformed into other compounds.

The theories of diabetes founded on these views ascribe its production either to an excessive formation of glycogen or to some defect in its transformation, the result being that grape sugar passes out of the body by the kidneys. It has long been known, both by experiment and by observation in disease, that injuries to certain parts of the nervous system, particularly the floor of the fourth ventricle in the brain, and that portion of the sympathetic nerve which sends branches to the liver and regulates its blood supply, are followed by the appearance of sugar in the urine. Hence certain pathologists seek an explanation for the disease in a morbid state of the parts of the nervous system whereby these particular nerves are either irritated or paralyzed and the flow of blood through the liver temporarily or permanently increased. It must, however, be remarked that, although in some instances the portions of the nervous system above mentioned are found after death to be involved in disease, this is by no means constant, and that in many cases of diabetes the *post mortem* appearances are entirely negative. While, therefore, considerable light

DIA—DIA

has by modern research been thrown upon this disease, its pathology cannot be regarded as settled. See NUTRITION. It ought to be mentioned that small quantities of sugar are frequently found in the urine in many diseases, and even in health after articles of food rich in sugar or starch have been eaten, as also in some forms of poisoning.

Little is known regarding the exciting causes of diabetes. Exposure to wet and cold, privation, depressing mental emotions, or mental overwork, the abuse of alcohol and of saccharine and starchy substances, have all been assigned as causes. It appears to be in some instances hereditary. It is most common among adults, and occurs much more frequently in males than in females.

The symptoms of diabetes are usually gradual in their onset, and the patient may suffer for a length of time before he thinks it necessary to apply for medical aid. The first symptoms which attract attention are failure of strength, and emaciation, along with great thirst and an increased amount and frequent passage of urine. From the normal quantity of from two to three pints in the twenty-four hours it may be increased to 10, 20, or 30 pints, or even more. It is usually of pale colour, and of thicker consistence than normal urine, possesses a decidedly sweet taste, and is of high specific gravity (1.03 to 1.05). It frequently gives rise to considerable irritation of the urinary passages.

By simple evaporation crystals of sugar may be obtained from diabetic urine, which also yields the characteristic chemical tests of sugar, while the amount of this substance can be accurately estimated by certain analytical processes. The quantity of sugar passed may vary from a few ounces to two or more pounds per diem, and it is found to be markedly increased after saccharine or starchy food has been taken. Sugar may also be found in the blood, saliva, tears, and in almost all the excretions of persons suffering from this disease. One of the most distressing symptoms is intense thirst, which the patient is constantly seeking to allay, the quantity of liquid consumed being in general enormous, and there is usually, but not invariably, a voracious appetite. The mouth is always parched, and a faint, sweetish colour may be evolved from the breath. The effect of the disease upon the general health is very marked, and the patient becomes more and more emaciated. He suffers from increasing muscular weakness, the temperature of his body is lowered, the skin is dry and harsh, the teeth are loosened or decay, while dyspeptic symptoms, constipation, and loss of sexual power are common accompaniments. There is in general great mental depression or irritability.

Diabetes as a rule advances comparatively slowly except in the case of young persons, in whom its progress is apt to be rapid. Various complications arise in the course of the disease, among which may be mentioned cataract, various cutaneous eruptions, kidney diseases, inflammatory chest affections, and especially pulmonary consumption, which is one of the most frequent modes of fatal termination in diabetes. Occasionally death occurs suddenly from exhaustion.

Diabetes is a very fatal form of disease, recovery being exceedingly rare. Nevertheless much may be done by appropriate treatment to mitigate the severity of the symptoms and to prolong life.

Cases may thus continue for years without material change to the worse, and in some rare instances it would seem that the disease is cured. The unfavourable cases are chiefly those occurring in young persons, also where serious chest or other complications arise, and especially where the disease itself is of severe character, the quantity of sugar passed being persistently large, and the patient losing flesh and strength rapidly.

With respect to the treatment of diabetes, the regula-

tion of the diet has by all authorities been regarded as a matter of the first importance, inasmuch as it has been proved beyond question that certain kinds of food have a powerful influence in aggravating the disease, more particularly those consisting largely of saccharine and starchy matter; and it may be stated generally that the various methods of treatment proposed aim at the elimination as far as possible of these constituents from the diet. Hence it is recommended that such articles as bread, potatoes, and all farinaceous foods, turnips, carrots, parsnips, and most fruits should be avoided; while animal food and soups, green vegetables, milk, cream, cheese, eggs, butter, and tea and coffee without sugar, may be taken with advantage. As a substitute for ordinary bread, which most persons find it difficult to do without for any length of time, bran bread, gluten bread, almond biscuits, and even well-browned toast or rusks are recommended. Alcoholic stimulants are of little or no use, but if prescribed should be in those forms containing the least saccharine matter, such as claret, Burgundy, brandy, or bitter ale.

Thirst may be mitigated by iced water, or water slightly acidulated with phosphoric acid. The employment of a diet consisting entirely of skimmed milk has been recommended by Dr Donkin of London, who has obtained good results from this method of treatment. The milk is administered in quantities of from 8 to 12 pints in the twenty-four hours, all other articles of diet being excluded.

The plan of treatment once proposed, of administering sugar in large quantity in diabetes, proved to be highly injurious, and is now abandoned.

Numerous medicinal substances have been employed in diabetes, but few of them are worthy of mention as possessed of any efficacy. Opium is often found of great service, its administration being followed with marked amelioration in all the symptoms, and, according to some high authorities, with cure of the disease. It is borne in diabetes in larger doses than usual, and from 5 to 12 grains or more may be taken in the twenty-four hours. In like manner codeia (one of the constituents of opium), in doses of half a grain increased to two or three grains three times a day, has been used with good effect.

In most cases, however, it is the dieting of the patient to which the physician has to look in dealing successfully with this formidable disease; and sufferers ought always to be impressed with the necessity of strictly abstaining from these articles of food which by general consent are allowed to exercise a hurtful influence in aggravating the symptoms.

In *diabetes insipidus*, there is constant thirst and an excessive flow of urine, which, however, is not found to contain any abnormal constituent. Its effects upon the system are often similar to those of diabetes mellitus, except that they are much less marked, the disease being in general very slow in its progress. In some cases the health appears to suffer very slightly. It is rarely a direct cause of death, but from its debilitating effects may predispose to serious and fatal complications. Little is known as to its pathology, but it is generally supposed to own a similar origin to diabetes mellitus. It is best treated by tonics and generous diet. Opium and valerian have been found beneficial. (J. O. A.)

DIAGORAS, born at Melos, was a writer of dithyrambic poetry. Religious in his youth, he became an atheist because a great wrong done upon him (the details of which are unknown) was left unpunished by the gods. In consequence of his blasphemous speeches, and especially from his publication of the *Mysteries*, he was condemned to death at Athens, and a price set upon his head. During his flight he perished by shipwreck. Aristophanes alludes to his atheism in the *Clouds*, 830 *sqq.*, and to his condemnation in the *Birds*, 1073. His date is not exactly known.

He could not have been, as is usually stated, a pupil of Democritus, as he was older than this philosopher, or certainly not younger. The circumstances of his death may have been confused with those of Protagoras. The writing in which he disclosed the Mysteries bore the name *φύσις λόγος*, or *ἀποσυγγίζοντες*. These are all the facts which are known of him, and none of his actual opinions are preserved. See Zeller, *Geschichte der Griechischen Philosophie*.

DIAGRAMS A diagram is a figure drawn in such a manner that the geometrical relations between the parts of the figure help us to understand relations between other objects. A few have been selected for description in this article on account of their greater geometrical significance.

Diagrams may be classed according to the manner in which they are intended to be used, and also according to the kind of analogy which we recognize between the diagram and the thing represented.

Diagrams of Illustration.

The diagrams in mathematical treatises are intended to help the reader to follow the mathematical reasoning. The construction of the figure is defined in words so that even if no figure were drawn the reader could draw one for himself. The diagram is a good one if those features which form the subject of the proposition are clearly represented. The accuracy of the drawing is therefore of smaller importance than its distinctness.

Metrical Diagrams.

Diagrams are also employed in an entirely different way—namely, for purposes of measurement. The plans and designs drawn by architects and engineers are used to determine the value of certain real magnitudes by measuring certain distances on the diagram. For such purposes it is essential that the drawing be as accurate as possible.

We therefore class diagrams as diagrams of illustration, which merely suggest certain relations to the mind of the spectator, and diagrams drawn to scale, from which measurements are intended to be made.

Methods in which diagrams are used for purposes of measurement are called Graphical methods.

Diagrams of illustration, if sufficiently accurate, may be used for purposes of measurement; and diagrams for measurement, if sufficiently clear, may be used for purposes of demonstration.

There are some diagrams or schemes, however, in which the form of the parts is of no importance, provided their connections are properly shown. Of this kind are the diagrams of electrical connections, and those belonging to that department of geometry which treats of the degrees of cyclosis, periphery, linkedness, and knottedness.

Diagrams purely Graphic and mixed Symbolic and Graphic.

Diagrams may also be classed either as purely graphical diagrams, in which no symbols are employed except letters or other marks to distinguish particular points of the diagrams, and mixed diagrams, in which certain magnitudes are represented, not by the magnitudes of parts of the diagram, but by symbols, such as numbers written on the diagram.

Thus in a map the height of places above the level of the sea is often indicated by marking the number of feet above the sea at the corresponding places on the map.

There is another method in which a line called a contour line is drawn through all the places in the map whose height above the sea is a certain number of feet, and the number of feet is written at some point or points of this line.

By the use of a series of contour lines, the height of a

great number of places can be indicated on a map by means of a small number of written symbols. Still this method is not a purely graphical method, but a partly symbolical method of expressing the third dimension of objects on a diagram in two dimensions.

Diagrams in Pairs.

In order to express completely by a purely graphical method the relations of magnitudes involving more than two variables, we must use more than one diagram. Thus in the arts of construction we use plans and elevations and sections through different planes, to specify the form of objects having three dimensions.

In such systems of diagrams we have to indicate that a point in one diagram corresponds to a point in another diagram. This is generally done by marking the corresponding points in the different diagrams with the same letter. If the diagrams are drawn on the same piece of paper we may indicate corresponding points by drawing a line from one to the other, taking care that this line of correspondence is so drawn that it cannot be mistaken for a real line in either diagram.

In the stereoscope the two diagrams, by the combined use of which the form of bodies in three dimensions is recognized, are projections of the bodies taken from two points so near each other that, by viewing the two diagrams simultaneously, one with each eye, we identify the corresponding points intuitively.

The method in which we simultaneously contemplate two figures, and recognize a correspondence between certain points in the one figure and certain points in the other, is one of the most powerful and fertile methods hitherto known in science. Thus in pure geometry the theories of similar, reciprocal, and inverse figures have led to many extensions of the science. It is sometimes spoken of as the method or principle of Duality.

DIAGRAMS IN KINEMATICS.

The study of the motion of a material system is much assisted by the use of a series of diagrams representing the configuration, displacement, and acceleration of the parts of the system.

Diagram of Configuration.

In considering a material system it is often convenient to suppose that we have a record of its position at any given instant in the form of a diagram of configuration.

The position of any particle of the system is defined by drawing a straight line or vector from the origin, or point of reference, to the given particle. The position of the particle with respect to the origin is determined by the magnitude and direction of this vector.

If in the diagram we draw from the origin (which need not be the same point of space as the origin for the material system) a vector equal and parallel to the vector which determines the position of the particle, the end of this vector will indicate the position of the particle in the diagram of configuration.

If this is done for all the particles, we shall have a system of points in the diagram of configuration, each of which corresponds to a particle of the material system, and the relative positions of any pair of these points will be the same as the relative positions of the material particles which correspond to them.

We have hitherto spoken of two origins or points from which the vectors are supposed to be drawn—one for the material system, the other for the diagram. These points, however, and the vectors drawn from them, may now be omitted, so that we have on the one hand the material

system and on the other a set of points, each point corresponding to a particle of the system, and the whole representing the configuration of the system at a given instant. This is called a diagram of configuration.

Diagram of Displacement.

Let us next consider two diagrams of configuration of the same system, corresponding to two different instants.

We call the first the initial configuration and the second the final configuration, and the passage from the one configuration to the other we call the displacement of the system. We do not at present consider the length of time during which the displacement was effected, nor the intermediate stages through which it passed, but only the final result—a change of configuration. To study this change we construct a diagram of displacement.

Let A, B, C be the points in the initial diagram of configuration, and A', B', C' be the corresponding points in the final diagram of configuration.

From o , the origin of the diagram of displacement, draw a vector oa equal and parallel to AA' , ob equal and parallel to BB' , oc to CC' , and so on.

The points, a, b, c , &c., will be such that the vector ab indicates the displacement of b relative to a , and so on. The diagram containing the points a, b, c , &c., is therefore called the diagram of displacement.

In constructing the diagram of displacement we have hitherto assumed that we know the absolute displacements of the points of the system. For we are required to draw a line equal and parallel to A_1A_2 , which we cannot do unless we know the absolute final position of A , with respect to its initial position. In this diagram of displacement there is therefore, besides the points a, b, c , &c., an origin, o , which represents a point absolutely fixed in space. This is necessary because the two configurations do not exist at the same time; and therefore to express their relative position we require to know a point which remains the same at the beginning and end of the time.

But we may construct the diagram in another way which does not assume a knowledge of absolute displacement or of a point fixed in space.

Assuming any point and calling it a , draw ak parallel and equal to B_1A_1 in the initial configuration, and from k draw lb parallel and equal to A_2B_2 in the final configuration. It is easy to see that the position of the point b relative to a will be the same by this construction as by the former construction, only we must observe that in this second construction we use only vectors such as A_1B_1, A_2B_2 , which represent the relative position of points both of which exist simultaneously, instead of vectors such as A_1A_2, B_1B_2 , which express the position of a point at one instant relative to its position at a former instant, and which therefore cannot be determined by observation, because the two ends of the vector do not exist simultaneously.

It appears therefore that the diagram of displacements, when drawn by the first construction includes an origin o , which indicates that we have assumed a knowledge of absolute displacements. But no such point occurs in the second construction, because we use such vectors only as we can actually observe. Hence the diagram of displacements *without an origin* represents neither more nor less than all we can ever know about the displacement of the material system.

Diagram of Velocity.

If the relative velocities of the points of the system are constant, then the diagram of displacement corresponding to an interval of a unit of time between the initial and the final configuration is called a diagram of relative velocity.

If the relative velocities are not constant, we suppose

another system in which the velocities are equal to the velocities of the given system at the given instant and continue constant for a unit of time. The diagram of displacements for this imaginary system is the required diagram of relative velocities of the actual system at the given instant.

It is easy to see that the diagram gives the velocity of any one point relative to any other, but cannot give the absolute velocity of any of them.

Diagram of Acceleration.

By the same process by which we formed the diagram of displacements from the two diagrams of initial and final configuration, we may form a diagram of changes of relative velocity from the two diagrams of initial and final velocities. This diagram may be called that of total accelerations in a finite interval of time.

By the same process by which we deduced the diagram of velocities from that of displacements we may deduce the diagram of rates of acceleration from that of total acceleration.

We have mentioned this system of diagrams in elementary kinematics because they are found to be of use especially when we have to deal with material systems containing a great number of parts, as in the kinetic theory of gases. The diagram of configuration then appears as a region of space swarming with points representing molecules, and the only way in which we can investigate it is by considering the number of such points in unit of volume in different parts of that region, and calling this the *density* of the gas.

In like manner the diagram of velocities appears as a region containing points equal in number but distributed in a different manner, and the number of points in any given portion of the region expresses the number of molecules whose velocities lie within given limits. We may speak of this as the velocity density.

Path and Hodograph.

When the number of bodies in the system is not so great, we may construct diagrams each of which represents some property of the whole course of the motion.

Thus if we are considering the motion of one particle relative to another, the point on the diagram of configuration which corresponds to the moving particle will trace out a continuous line called the path of the particle.

On the diagram of velocity the point corresponding to the moving particle will trace another continuous line called the hodograph of the particle.

The hodograph was invented and used with great success by Sir W. R. Hamilton as a method of studying the motions of bodies.

DIAGRAMS OF STRESS.

Graphical methods are peculiarly applicable to statical questions, because the state of the system is constant, so that we do not need to construct a series of diagrams corresponding to the successive states of the system.

The most useful of these applications relates to the equilibrium of plane framed structures. Two diagrams are used, one called the diagram of the frame and the other called the diagram of stress.

The structure itself consists of a number of separable pieces or links jointed together at their extremities. In practice these joints have friction, or may be made purposely stiff, so that the force acting at the extremity of a piece may not pass exactly through the axis of the joint; but as it is unsafe to make the stability of the structure depend in any degree upon the stiffness of joints, we assume in our calculations that all the joints are perfectly smooth, and therefore that the force acting on the end of any link passes through the axis of the joint.

The axes of the joints of the structure are represented by points in the diagram of the frame.

The link which connects two joints in the actual structure may be of any shape, but in the diagram of the frame it is represented by a straight line joining the points representing the two joints.

If no force acts on the link except the two forces acting through the centres of the joints, these two forces must be equal and opposite, and their direction must coincide with the straight line joining the centres of the joints.

If the force acting on either extremity of the link is directed towards the other extremity, the stress on the link is called pressure and the link is called a strut. If it is directed away from the other extremity, the stress on the link is called tension and the link is called a tie.

In this case, therefore, the only stress acting in a link is a pressure or a tension in the direction of the straight line which represents it in the diagram of the frame, and all that we have to do is to find the magnitude of this stress.

In the actual structure, gravity acts on every part of the link, but in the diagram we substitute for the actual weight of the different parts of the link, two weights which have the same resultant acting at the extremities of the link.

We may now treat the diagram of the frame as composed of links without weight, but loaded at each joint with a weight made up of portions of the weights of all the links which meet in that joint.

If any link has more than two joints we may substitute for it in the diagram an imaginary stiff frame, consisting of links, each of which has only two joints.

The diagram of the frame is now reduced to a system of points, certain pairs of which are joined by straight lines, and each point is in general acted on by a weight or other force acting between it and some point external to the system.

To complete the diagram we may represent these external forces as links, that is to say, straight lines joining the points of the frame to points external to the frame. Thus each weight may be represented by a link joining the point of application of the weight with the centre of the earth.

But we can always construct an imaginary frame having its joints in the lines of action of these external forces, and this frame, together with the real frame and the links representing external forces, which join points in the one frame to points in the other frame, make up together a complete self-strained system in equilibrium, consisting of points connected by links acting by pressure or tension. We may in this way reduce any real structure to the case of a system of points with attractive or repulsive forces acting between certain pairs of these points, and keeping them in equilibrium.

The direction of each of these forces is sufficiently indicated by that of the line joining the points, so that we have only to determine its magnitude.

We might do this by calculation, and then write down on each link the pressure or the tension which acts in it.

We should in this way obtain a mixed diagram in which the stresses are represented graphically as regards direction and position, but symbolically as regards magnitude.

But we know that a force may be represented in a purely graphical manner by a straight line in the direction of the force containing as many units of length as there are units of force in the force. The end of this line is marked with an arrow head to show in which direction the force acts.

According to this method each force is drawn in its proper position in the diagram of configuration of the frame. Such a diagram might be useful as a record of the result of calculation of the magnitude of the forces, but it would be of no use in enabling us to test the correctness of the calculation.

But we have a graphical method of testing the equilibrium of any set of forces acting at a point. We draw in series a set of lines parallel and proportional to these forces. If these lines form a closed polygon the forces are in equilibrium. We might in this way form a series of polygons of forces, one for each joint of the frame. But in so doing we give up the principle of drawing the line representing a force from the point of application of the force, for all the sides of the polygon cannot pass through the same point, as the forces do.

We also represent every stress twice over, for it appears as a side of both the polygons corresponding to the two joints between which it acts.

But if we can arrange the polygons in such a way that the sides of any two polygons which represent the same stress coincide with each other, we may form a diagram in which every stress is represented in direction and magnitude, though not in position, by a single line which is the common boundary of the two polygons which represent the joints at the extremities of the corresponding piece of the frame.

We have thus obtained a pure diagram of stress in which no attempt is made to represent the configuration of the material system, and in which every force is not only represented in direction and magnitude by a straight line, but the equilibrium of the forces at any joint is manifest by inspection, for we have only to examine whether the corresponding polygon is closed or not.

The relations between the diagram of the frame and the diagram of stress are as follows —

To every link in the frame corresponds a straight line in the diagram of stress which represents in magnitude and direction the stress acting in that link.

To every joint of the frame corresponds a closed polygon in the diagram, and the forces acting at that joint are represented by the sides of the polygon taken in a certain cyclical order. The cyclical order of the sides of the two adjacent polygons is such that their common side is traced in opposite directions in going round the two polygons.

The direction in which any side of a polygon is traced is the direction of the force acting on that joint of the frame which corresponds to the polygon, and due to that link of the frame which corresponds to the side.

This determines whether the stress of the link is a pressure or a tension.

If we know whether the stress of any one link is a pressure or a tension, this determines the cyclical order of the sides of the two polygons corresponding to the ends of the links, and therefore the cyclical order of all the polygons, and the nature of the stress in every link of the frame.

Definition of Reciprocal Diagrams.

When to every point of concurrence of the lines in the diagram of stress corresponds a closed polygon in the skeleton of the frame, the two diagrams are said to be reciprocal.

The first extensions of the method of diagrams of forces to other cases than that of the funicular polygon were given by Rankine in his *Applied Mechanics* (1857). The method was independently applied to a large number of cases by Mr W. P. Taylor, a practical draughtsman in the office of the well-known contractor Mr J. B. Cochrane, and by Professor Clerk Maxwell in his lectures in King's College, London. In the *Phil. Mag.* for 1864 the latter pointed out the reciprocal properties of the two diagrams, and in a paper on "Reciprocal Figures, Frames, and Diagrams of Forces," *Trans. R. S. Edinburgh*, vol. xxvi. (1870), he showed the relation of the method to Airy's function of stress and to other mathematical methods.

Professor Fleeming Jenkin has given a number of applications of the method to practice (*Trans. R. S. Edin.*, vol. xiv.)

Cremona (*Le figure reciproche nella statica grafica*, Milan, 1872) has deduced the construction of reciprocal figures from the theory of the two components of a wrench as developed by Mobius.

Culmann, in his *Graphische Statik*, makes great use of diagrams of forces, some of which, however, are not reciprocal.

M. Maurice Levy in his *Statique Graphique* (Paris, 1874) has treated the whole subject in an elementary but copious manner.

Mr R. H. Bow, C.E., F.R.S.E., in his work on *The Economics of Construction in relation to Framed Structures*, 1873, has materially simplified the process of drawing a diagram of stress reciprocal to a given frame acted on by a system of equilibrating external forces.

Instead of lettering the joints of the frame, as is usually done, or the links of the frame, as was the writer's custom, he places a letter in each of the polygonal areas inclosed by the links of the frame, and also in each of the divisions of surrounding space as separated by the lines of action of the external forces.

When one link of the frame crosses another, the point of apparent intersection of the links is treated as if it were a real joint, and the stresses of each of the intersecting links are represented twice in the diagram of stress, as the opposite sides of the parallelogram which corresponds to the point of intersection.

FIG 1 —Diagram of Configuration.

FIG 2 —Diagram of Stress.

This method is followed in the lettering of the diagram of configuration (fig. 1), and the diagram of stress (fig. 2) of the linkwork which Professor Sylvester has called a quadruplane.

In fig. 1 the real joints are distinguished from the places where one link appears to cross another by the little circles O, P, Q, R, S, T, V.

The four links RSTV form a "contraparallelogram" in which $RS = TV$ and $RV = ST$.

The triangles ROS, RPV, TQS are similar to each other. A fourth triangle (TNV), not drawn in the figure, would complete the quadruplane. The four points O, P, N, Q form a parallelogram whose angle POQ is constant and equal to $\pi - \angle SOR$. The product of the distances OP and OQ is constant.

The linkwork may be fixed at O. If any figure is traced by P, Q will trace the inverse figure, but turned round O through the constant angle POQ.

In the diagram forces Pp, Qq are balanced by the force Oo at the fixed point. The forces Pp and Qq are necessarily inversely as OP and OQ, and make equal angles with those lines.

Every closed area formed by the links or the external forces in the diagram of configuration is marked by a letter which corresponds to a point of concurrence of lines in the diagram of stress.

The stress in the link which is the common boundary of two areas is represented in the diagram of stress by the line joining the points corresponding to those areas.

When a link is divided into two or more parts by lines crossing it, the stress in each part is represented by a different line for each part, but as the stress is the same throughout the link these lines are all equal and parallel. Thus in the figure the stress in RV is represented by the four equal and parallel lines HI, FG, DE, and AB.

If two areas have no part of their boundary in common the letters corresponding to them in the diagram of stress are not joined by a straight line. If, however, a straight line were drawn between them, it would represent in direction and magnitude the resultant of all the stresses in the links which are cut by any line, straight or curved, joining the two areas.

For instance the areas F and C in fig. 1 have no common boundary, and the points F and C in fig. 2 are not joined by a straight line. But every path from the area F to the area C in fig. 1 passes through a series of other areas, and each passage from one area into a contiguous area corresponds to a line drawn in the diagram of stress. Hence the whole path from F to C in fig. 1 corresponds to a path formed of lines in fig. 2 and extending from F to C, and the resultant of all the stresses in the links cut by the path is represented by FC in fig. 2.

Automatic Description of Diagrams.

There are many other kinds of diagrams in which the two co-ordinates of a point in a plane are employed to indicate the simultaneous values of two related quantities.

If a sheet of paper is made to move, say horizontally, with a constant known velocity, while a tracing point is made to move in a vertical straight line, the height varying as the value of any given physical quantity, the point will trace out a curve on the paper from which the value of that quantity at any given time may be determined.

This principle is applied to the automatic registration of phenomena of all kinds, from those of meteorology and terrestrial magnetism to the velocity of cannon-shot, the vibrations of sounding bodies, the motions of animals, voluntary and involuntary, and the currents in electric telegraphs.

Indicator Diagram.

In Watt's indicator for steam engines the paper does not move with a constant velocity, but its displacement is proportional to that of the piston of the engine, while that of the tracing point is proportional to the pressure of the steam. Hence the co-ordinates of a point of the curve traced on the diagram represent the volume and the pressure of the steam in the cylinder. The indicator-diagram not only supplies a record of the pressure of the steam at each stage of the stroke of the engine, but indicates the work done by the steam in each stroke by the area inclosed by the curve traced on the diagram.

The indicator-diagram was invented by James Watt as a method of estimating the work done by an engine. It was afterwards used by Clapeyron to illustrate the theory of

heat, and this use of it was greatly developed by Rankine in his work on the steam engine

The use of diagrams in thermodynamics has been very completely illustrated by Prof. J. Willard Gibbs (*Connec-*

ticut Acad. Sci., vol. iii), but though his methods throw much light on the general theory of diagrams as a method of study, they belong rather to thermodynamics than to the present subject. (J. C. M.)

D I A L L I N G

DIALLING, sometimes called *gnomonics*, is a branch of applied mathematics which treats of the construction of sun-dials, that is, of those instruments, either fixed or portable, which determine the divisions of the day by the motion of the shadow of some object on which the sun's rays fall.

It must have been one of the earliest applications of a knowledge of the apparent motion of the sun; though for a long time men would probably be satisfied with the division into morning and afternoon as marked by sun-rise, sun-set, and the greatest elevation.

History—The earliest mention of a sun-dial is found in Isaiah xxxviii. 8: "Behold, I will bring again the shadow of the degrees which is gone down in the *sun-dial* of Ahaz ten degrees backward." The date of this would be about 700 years before the Christian era, but we know nothing of the character or construction of the instrument.

The earliest of all sun dials of which we have any certain knowledge was the *hemicycle*, or hemisphere, of the Chaldean astronomer Berosus, who probably lived about 340 B.C. It consisted of a hollow hemisphere placed with its rim perfectly horizontal, and having a bead, or globule, fixed in any way at the centre. So long as the sun remained above the horizon the shadow of the bead would fall on the inside of the hemisphere, and the path of the shadow during the day would be approximately a circular arc. This arc, divided into twelve equal parts, determined twelve equal intervals of time for that day. Now, supposing this were done at the time of the solstices and equinoxes, and on as many intermediate days as might be considered sufficient, and then curve lines drawn through the corresponding points of division of the different arcs, the shadow of the bead falling on one of these curve lines would mark a division of time for that day, and thus we should have a sun-dial which would divide each period of daylight into twelve equal parts.

These equal parts were called *temporary hours*; and, since the duration of daylight varies from day to day, the temporary hours of one day would differ from those of another; but this inequality would probably be disregarded at that time, and especially in countries where the variation between the longest summer day and the shortest winter day is much less than in our climates.

The dial of Berosus remained in use for centuries. The Arabians, as appears from the work of Albateguius, still followed the same construction about the year 900 A.D. Four of these dials have in modern times been found in Italy. One, discovered at Tivoli in 1746, is supposed to have belonged to Cicero, who, in one of his letters, says that he had sent a dial of this kind to his villa near Tuseulum. The second and third were found in 1751—one at Castel-Nuovo, and the other at Rignauo; and a fourth was found in 1762 at Pompeii. G. H. Martin, the author of a dissertation in German on the dials of the ancients, says that this dial was made for the latitude of Memphis; it may therefore be the work of Egyptians, perhaps constructed in the school of Alexandria.

It is curious that no sun-dial has been found among the antiquities of Egypt, and their sculptures give no indication of any having existed. It has, however, been supposed that the numerous obelisks found everywhere were erected in honour of the sun and employed as gnomons.

Herodotus has recorded that the Greeks derived from the Babylonians the use of the gnomon, but the great progress made by the Greeks in geometry enabled them in later times to construct dials of great complexity, some of which remain to us, and are proofs, not only of extensive knowledge, but also of great ingenuity.

Ptolemy's *Syntaxis* treats of the construction of dials by means of his *analemma*, an instrument which solved a variety of astronomical problems. The constructions given by him were sufficient for regular dials, that is, horizontal dials, or vertical dials facing east, west, north, or south, and these are the only ones he treats of. It is certain, however, that the ancients were able to construct declining dials, as is shown by that most interesting monument of ancient gnomonics—the Tower of the Winds—which is still in existence at Athens. This is a regular octagon, on the faces of which the eight principal winds are represented, and over them eight different dials—four facing the cardinal points and the other four facing the intermediate directions. The date of the dials is long subsequent to that of the tower; for Vitruvius, who describes the tower in the sixth chapter of his first book, says nothing about the dials, and as he has described all the dials known in his time, we must believe that the dials of the tower did not then exist. The tower and its dials are described by Stuart in his *Antiquities of Athens*. The hours are still the temporary hours, or, as the Greeks called them, *hectemoria*.

As already stated, the learning and ingenuity of the Greeks enabled them to construct dials of various forms—among others, dials of suspension intended for travellers; but these are only spoken of and not explained; they may have been like our ring-dials.

The Romans were neither geometers nor astronomers, and the science of gnomonics did not flourish among them. The first sun-dial erected at Rome was in the year 290 B.C., and this Papirius Cursor had taken from the Samnites. A dial which Valerius Messala had brought from Catania, the latitude of which is five degrees less than that of Rome, was placed in the forum in the year 261 B.C. The first dial actually constructed at Rome was in the year 164 B.C., by order of Q. Marcius Philippus, but, as no other Roman has written on gnomonics, this was perhaps the work of a foreign artist. If, too, we remember that the dial found at Pompeii was made for the latitude of Memphis, and consequently less adapted to its position than that of Catania to Rome, we may infer that mathematical knowledge was not cultivated in Italy.

The Arabians were much more successful. They attached great importance to gnomonics, the principles of which they had learned from the Greeks, but they greatly simplified and diversified the Greek constructions. One of their writers, Abul-Hassau, who lived about the beginning of the 13th century, taught them how to trace dials on cylindrical, conical, and other surfaces. He even introduced *equal* or *equinoctial hours*, but the idea was not supported, and the temporary hours alone continued in use.

Where or when the great and important step already conceived by Abul-Ha-san, and perhaps by others, of reckoning by *equal hours* was generally adopted cannot now be determined. The history of gnomonics from the 13th to the beginning of the 16th century is almost a blank, and during that time the change took place. We

can see, however, that the change would necessarily follow the introduction of clocks and other mechanical methods of measuring time; for, however imperfect these were, the hours they marked would be of the same length in summer and in winter, and the discrepancy between these equal hours and the temporary hours of the sun-dial would soon be too important to be overlooked. Now, we know that a balance clock was put up in the palace of Charles V. of France about the year 1370, and we may reasonably suppose that the new sun-dials came into general use during the 14th and 15th centuries.

Among the earliest of the modern writers on gnomonics must be named Sebastian Munster, a cordelier who published his *Hiorologographia* at Basel in 1531. He gives a number of correct rules, but without demonstrations. Among his inventions was a moon-dial,¹ but this does not admit of much accuracy.

During the 17th century dialling was discussed at great length by all writers on astronomy. Clavius devotes a quarto volume of 800 pages entirely to the subject. This was published in 1612, and may be considered to contain all that was known at that time.

In the 18th century clocks and watches began to supersede sun-dials, and these have gradually fallen into disuse except as an additional ornament to a garden, or in remote country districts where the old dial on the church tower still serves as an occasional check on the modern clock by its side. The art of constructing dials may now be looked upon as little more than a mathematical recreation.

General Principles—The diurnal and the annual motions of the earth are the elementary astronomical facts on which dialling is founded. That the earth turns upon its axis uniformly from west to east in 24 hours, and that it is carried round the sun in one year at a nearly uniform rate, is, we know, the correct way of expressing these facts. But the effect will be precisely the same, and it will suit our purpose better, and make our explanations easier, if we adopt the ideas of the ancients, of which our senses furnish apparent confirmation, and assume the earth to be fixed. Then, the sun and stars revolve round the earth's axis uniformly from east to west once a day,—the sun lagging a little behind the stars, making its day some 4 minutes longer, so that at the end of the year it finds itself again in the same place, having made a complete revolution of the heavens relatively to the stars from west to east.

The fixed axis about which all these bodies revolve daily is a line through the earth's centre; but the radius of the earth is so small, compared with the enormous distance of the sun, that, if we draw a parallel axis through any point of the earth's surface, we may safely look on that as being the axis of the celestial motions. The error in the case of the sun would not, at its maximum, that is, at 6 A.M. and 6 P.M., exceed half a second of time, and at noon would vanish.

An axis so drawn is in the plane of the meridian, and points, as we know, to the pole,—its elevation being equal to the latitude of the place.

The diurnal motion of the stars is strictly uniform, and so would that of the sun be if the daily retardation of about 4 minutes, spoken of above, were always the same. But this is constantly altering, so that the time, as measured by the sun's motion, and also consequently as measured by a sun dial, does not move on at a strictly uniform pace. This irregularity, which is slight, would be of little consequence in the ordinary affairs of life, but clocks and

watches being mechanical measures of time could not, except by extreme complication, be made to follow this irregularity, even if desirable, which is not the case.

The clock is constructed to mark uniform time in such wise that the length of the clock day shall be the average of all the solar days in the year. Four times a year the clock and the sun-dial agree exactly; but the sun-dial, now going a little slower, now a little faster, will be sometimes behind, sometimes before the clock—the greatest accumulated difference being about 16 minutes for a few days in November, but on the average much less. The four days on which the two agree are April 15, June 15, September 1, and December 24.

Clock-time is called *mean time*, that marked by the sun-dial is called *apparent time*, and the difference between them is the *equation of time*. It is given in most calendars and almanacs, frequently under the heading "clock slow," "clock fast." When the time by the sun-dial is known, the equation of time will at once enable us to obtain the corresponding clock time, or *vice versa*.

Atmospheric refraction introduces another error, by altering the apparent position of the sun; but the effect is too small to need consideration in the construction of an instrument which, with the best workmanship, does not after all admit of very great accuracy.

The general principles of dialling will now be readily understood. The problem before us is the following:—A rod, or *style*, as it is called, being firmly fixed in a direction parallel to the earth's axis, we have to find how and where points or lines of reference must be traced on some fixed surface behind the style, so that when the shadow of the style falls on a certain one of these lines we may know that at that moment it is solar noon,—that is, that the plane through the style and through the sun then coincides with the meridian; again, that when the shadow reaches the next line of reference, it is 1 o'clock by solar time, or, which comes to the same thing, that the above plane through the style and through the sun has just turned through the twenty-fourth part of a complete revolution; and so on for the subsequent hours,—the hours before noon being indicated in a similar manner. The style and the surface on which these lines are traced together constitute the dial.

The position of an intended sun-dial having been selected—whether on church tower, south front of farm-stead, or garden wall—the surface must be prepared, if necessary, to receive the hour-lines.

The chief, and in fact the only practical difficulty will be the accurate fixing of the style, for on its accuracy the value of the instrument depends.

It must be in the meridian plane, and must make an angle with the horizon equal to the latitude of the place. The latter condition will offer no difficulty, but the exact determination of the meridian plane which passes through the point where the style is fixed to the surface is not so simple. We shall, further on, show how this may be done; and, in the meantime, we shall assume that we have found the true position, and have firmly fixed the style to the dial and secured it there by cross wires, or by other means. The style itself will be usually a strong metal wire whose thickness may vary with circumstances; and when we speak of the shadow cast by the style it must always be understood that the middle line of the thin band of shade is meant.

The point where the style meets the dial is called the centre of the dial. It is the centre from which all the hour-lines radiate.

The position of the 11 o'clock line is the most important to determine accurately, since all the others are usually made to depend on this one. We cannot trace it correctly

¹ In one of the Courts of Queen's College, Cambridge, there is an elaborate sun-dial dating from the end of the 17th or beginning of the 18th century, and around it a series of numbers which make it available as a moon-dial when the moon's age is known.

on the dial until the style has been itself accurately fixed in its proper place, as will be explained hereafter. When that is done the XII o'clock line will be found by the intersection of the dial surface with the vertical plane which contains the style; and the most simple way of drawing it on the dial will be by suspending a plummet from some point of the style whence it may hang freely, and waiting until the shadows of both style and plumb line coincide on the dial. This single shadow will be the XII o'clock line.

In one class of dials, namely, all the vertical ones, the XII o'clock line is simply the vertical line from the centre; it can, therefore, at once be traced on the dial face by using a fine plumb line.

The XII o'clock line being traced, the easiest and most accurate method of tracing the other hour lines would at the present day when good watches are common, be by marking where the shadow of the style falls when 1, 2, 3, &c., hours have elapsed since noon, and the next morning by the same means the forenoon hour lines could be traced; and in the same manner the hours might be subdivided into halves and quarters, or even into minutes.

But formerly, when watches were not, the tracing of the I, II, III, &c. o'clock lines was done by calculating the angle which each of these lines would make with the XII o'clock line. Now, except in the simple cases of a horizontal dial or of a vertical dial facing a cardinal point, this would require long and intricate calculations, or elaborate geometrical constructions, implying considerable mathematical knowledge, but also introducing increased chances of error. The chief source of error would lie in the uncertainty of the data; for the position of the dial-plane would have to be found before the calculations began,—that is, it would be necessary to know exactly by how many degrees it declined from the south towards the east or west, and by how many degrees it inclined from the vertical. The ancients, with the means at their disposal, could obtain these results only very roughly.

Dials received different names according to their position:—

Horizontal dials, when traced on a horizontal plane;

Vertical dials, when on a vertical plane facing one of the cardinal points;

Vertical declining dials, on a vertical plane not facing a cardinal point;

Inclining dials, when traced on planes neither vertical nor horizontal (these were further distinguished as *reclining* when leaning backwards from an observer, *proclining* when leaning forwards);

Equinoctial dials, when the plane is at right angles to the earth's axis, &c. &c.

We shall limit ourselves to an investigation of the simplest and most usual of these cases, referring the reader, for further details, to the later works given at the end of this article.

Dial Construction—A very correct view of the problem of dial construction may be obtained as follows:—

Conceive a transparent cylinder (fig 1) having an axis AB parallel to the axis of the earth. On the surface of the cylinder let equidistant generating lines be traced 15° apart, one of them XII being in the meridian plane through AB, and the others I, II, III, &c., following in the order of the sun's motion.

Then the shadow of the line AB will obviously fall on the line XII. XII at apparent noon, on the line I...I at one hour after noon, on II...II at two hours after noon, and so on. If now the cylinder be cut by any plane MN representing the plane on which the dial is to be traced, the shadow of AB will be intercepted by this plane, and fall on the lines AXII, AI, AII, &c.

The construction of the dial consists in determining the angles made by AI, AII, &c. with AXII; the line AXII itself, being in the vertical plane through AB, may be supposed known.

For the purposes of actual calculation, perhaps a trans-

parent sphere will, with advantage, replace the cylinder, and we shall here apply it to calculate the angles made by the hour line with the XII o'clock line in the two cases of a horizontal dial and of a vertical south dial.

Fig 1.

Horizontal Dial.—Let PEp (fig 2), the axis of the supposed transparent sphere, be directed towards the north and south poles of the heavens. Draw the two great circles, HMA, QMa,

Fig 2.

the former horizontal, the other perpendicular to the axis Ep, and therefore coinciding with the plane of the equator. Let EZ be vertical, then the circle QZP will be the meridian, and by its intersection A with the horizontal will determine the XII o'clock line EA. Next divide the equatorial circle QMa into 24 equal parts ab, &c., of 15° each, beginning from the meridian Pa, and through the various points of division and the poles draw the great circles Pbp, Pcp, &c. These will exactly correspond to the equidistant generating lines on the cylinder in the previous construction, and the shadow of the style will fall on these circles after successive intervals of 1, 2, 3, &c. hours from noon. If they meet the horizontal in the points B, C, D &c., then EB, EC, ED, &c. will be the I, II, III, &c. hour lines required, and the problem of the horizontal dial consists in calculating the angles which these lines make with the XII o'clock line EA, whose position is known. The spherical triangles PAB, PAC, &c., enable us to do this readily. They are all right-angled at A, the side PA is the latitude of the place, and the angles APB, APC, &c., are respectively 15° , 30° , &c., then

$$\begin{aligned}\tan. AB &= \tan 15^\circ \sin \text{latitude}, \\ \tan. AC &= \tan 30^\circ \sin \text{latitude}, \\ &\text{\&c., \&c.}\end{aligned}$$

These determine the sides AB, AC, &c. that is, the angles AEB, AEC, &c., required.

For examples, let us find the angles made by the 1 o'clock line at the following places—Madras, London, Edinburgh, and Hammerfest (Norway).

the meridian plane will be the XII o'clock line, and the horizontal line EM¹ will be the VI o'clock line. Now, as in the previous problem, divide the equatorial circle into 24 equal arcs of 15° each, beginning at a, viz., ab, bc, &c.,—each quadrant aM, MQ, &c., containing six,—then through each point of division

Fig. 4.

and through the axis Pp draw a plane cutting the sphere in 24 equidistant great circles. As the sun revolves round the axis the shadow of the axis will successively fall on these circles at intervals of one hour, and if these circles cross the vertical circle ZMA in the points A, B, C, &c., the shadow of the lower portion Ep of the axis will fall on the lines EA, EB, EC, &c., which will therefore be the required hour-lines on the vertical dial, Ep being the style.

There is no necessity for going beyond the VI o'clock hour-line on each side of noon; for, in the winter months the sun sets earlier than 6 o'clock, and in the summer months it passes behind the plane of the dial before that time, and is no longer available.

It remains to show how the angles AEB, AEC, &c., may be calculated.

The spherical triangles pAB, pAC, &c., will give us a simple rule. These triangles are all right-angled at A, the side pA, equal to ZP, is the co-latitude of the place, that is, the difference between the latitude and 90°, and the successive angles ApB, ApC, &c. are 15°, 30°, &c., respectively. Then

$$\tan. AB = \tan. 15^\circ \sin \text{co-latitude};$$

or more simply,

$$\begin{aligned} \tan. AB &= \tan. 15^\circ \cos \text{latitude}, \\ \tan. AC &= \tan. 30^\circ \cos \text{latitude}, \\ &\text{\&c. , \&c.} \end{aligned}$$

and the arcs AB, AC so found are the measure of the angles AEB, AEC, &c., required.

We shall, as examples, calculate the I o'clock hour angle AEB for each of the four places we had already taken in the horizontal dial.

Madras (13° 4' N lat)	London (51° 30' N lat.)
Log tan 15°. . . 9 42805	Log. tan 15°. . . 9 42805
Log cos. 13° 4'. . . 9 98861	Log cos 51° 30' . . 9 79415
Log tan 14° 38' . . . 9 41666	Log tan. 9° 28'. . . 9 22220
Edinburgh (55° 57' N. lat)	Hammerfest (73° 40' N lat)
Log tan. 15°. . . 9 42805	Log tan 15°. . . 9 42805
Log cos. 55° 57'. . . 9 74812	Log cos. 73° 40' . . 9 44005
Log. tan. 8° 32'. . . 9 17617	Log tan 4° 19'. . . 8 87710

In this case the angles diminish as the latitudes increase, the opposite result to that of the horizontal dial.

Inclining, Reclining, &c., Dials.—We shall not enter into the calculation of these cases. Our imaginary sphere being, as before supposed, constructed with its centre at the centre of the dial, and all the hour-circles traced upon it, the intersection of these hour-circles with the plane of the

dial will determine the hour-lines just as in the previous cases, but the triangles will no longer be right angled, and the simplicity of the calculation will be lost, the chances of error being greatly increased by the difficulty of drawing the dial-plane in its true position on the sphere, since that true position will have to be found from observations which can be only roughly performed.

In all these cases, and in cases where the dial surface is not a plane, and the hour-lines, consequently, are not straight lines, the only safe practical way is to mark rapidly on the dial a few points (one is sufficient when the dial face is plane) of the shadow at the moment when a good watch shows that the hour has arrived, and afterwards connect these points with the centre by a continuous line. Of course the style must have been accurately fixed in its true position before we begin.

Equatorial Dial.—The name equatorial dial is given to one whose plane is at right angles to the style, and therefore parallel to the equator. It is the simplest of all dials. A circle (fig 5) divided into 24 equal arcs is placed at right angles to the style, and hour divisions are marked upon it. Then if care be taken that the style point accurately to the pole, and that the noon division coincide with the meridian plane, the shadow of the style will fall on the other divisions, each at its proper time. The divisions must be marked on both sides of the dial, because the sun will shine on opposite sides in the summer and in the winter months, changing at each equinox.

Fig 5

To find the Meridian Plane.—We have, so far, assumed the meridian plane to be accurately known; we shall proceed to describe some of the methods by which it may be found.

The mariner's compass may be employed as a first rough approximation. It is well known that the needle of the compass, when free to move horizontally, oscillates upon its pivot and settles in a direction termed the magnetic meridian. This does not coincide with the true north and south line, but the difference between them is generally known with tolerable accuracy, and is called the variation of the compass. The variation differs widely at different parts of the surface of the earth, being now about 20° W in London, 7° W. in New York, and 17° E in San Francisco. Nor is the variation at any place stationary, though the change is slow. We said that *now* the variation in London is about 20° W.; in 1837 it was about 24° W; and there is even a small daily oscillation which takes place about the mean position, but too small to need notice here.

With all these elements of uncertainty, it is obvious that the compass can only give a rough approximation to the position of the meridian, but it will serve to fix the style so that only a small further alteration will be necessary when a more perfect determination has been made.

A very simple practical method is the following:—

Place a table (fig. 6), or other plane surface, in such a position that it may receive the sun's rays both in the morning and in the afternoon. Then carefully level the surface by means of a spirit-level. This must be done very accurately, and the table in that position made perfectly secure, so that there be no danger of its shifting during the day.

Next, suspend a plummet SH from a point S, which must be rigidly fixed. The extremity H, where the plummet just meets the surface, should be somewhere near the

¹ EM is obviously horizontal, since M is the intersection of two great circles ZM, QM, each at right angles to the vertical plane QZP.

Madras (13° 4' N lat.)		London (51° 30' N lat.)	
Log tan 15° ...	9.42865	Log tan 15° ...	9.42865
Log sin 15° 4' ...	9.37427	Log sin 51° 30' ...	9.89354
Log tan 3° 25' ...	8.78232	Log tan 11° 51' ...	9.32159
Edinburgh (55° 57' N lat.)		Hammerfest (73° 49' N lat.)	
Log tan 15° ...	9.42865	Log tan 15° ...	9.42865
Log sin 55° 57' ...	9.91832	Log sin 73° 49' ...	9.98211
Log tan 12° 21' ...	9.31637	Log tan 14° 25' ...	9.41016

Thus the 1 o'clock hour line EB must make an angle on a Madras dial of only 3° 25' with the meridian EA, 11° 51' on a London dial, 12° 21' at Edinburgh, and 14° 25' at Hammerfest. In the same way may be found the angles made by the other hour lines.

The calculations of these angles must extend throughout one quadrant from noon to 6 o'clock, but need not be carried further, because all the other hour-lines can at once be deduced from these. —In the first place the dial is symmetrically divided by the meridian, and therefore two times equidistant from noon will have their hour lines equidistant from the meridian, thus the 11 o'clock line and the 1 o'clock line must make the same angles with it, the 10 o'clock the same as the 2 o'clock, and so on. And next, the 24 great circles, which were drawn to determine these lines, are in reality only 12, for clearly the great circle which gives 1 o'clock after midnight, and that which gives 1 o'clock after noon, are one and the same, and so also for the other hours. Therefore the hour lines between 6 in the evening and 6 in the next morning are the prolongations of the remaining twelve.

Let us now remove the imaginary sphere with all its circles, and retain only the style EP and the plane BMA with the lines traced on it, and we shall have the horizontal dial.

On the longest day in London the sun rises a little after 4 o'clock, and sets a little before 8 o'clock, there is therefore no necessity for extending a London dial beyond those hours. At Edinburgh the limits will be a little longer, while at Hammerfest, which is within the Arctic circle, the whole circuit will be required.

Instead of a wire style it is often more convenient to use a metal plate from one quarter to half an inch in thickness. This plate, which is sometimes in the form of a right-angled triangle, must have an acute angle equal to the latitude of the place, and, when properly fixed in a vertical position on the dial, its two faces must coincide with the meridian plane, and the sloping edges formed by the thickness of the plate must point to the pole and form two parallel styles. Since there are two styles, there must be two dials, or rather two half dials, because a little consideration will show that, owing to the thickness of the plate, these styles will only one at a time cast a shadow. Thus the eastern edge will give the shadow for all hours before 6 o'clock in the morning. From 6 o'clock until noon the western edge will be used. At noon, it will change again to the eastern edge until 6 o'clock in the evening, and finally the western edge for the remaining hours of daylight.

The centres of the two dials will be at the points where the styles meet the dial face, but, in drawing the hour-lines, we must be careful to draw only those lines for which the corresponding style is able to give a shadow as explained above. The dial will thus have the appearance of a single dial plate, and there will be no confusion (see fig. 3).

Fig. 3.

The line of demarcation between the shadow and the light will be better defined than when a wire style is used; but the indications by this double dial will always be one minute too fast in the morning and one minute too slow in the afternoon. This is owing to the magnitude of the

sun, whose angular breadth is half a degree. The well-defined shadows are given, not by the centre of the sun, as we should require them, but by the forward limb in the morning and by the backward one in the afternoon; and the sun takes just about a minute to advance through a space equal to its half-breadth.

Dials of this description are frequently met with in the country. Placed on an ornamental pedestal some 4 feet high, they form a pleasing and useful addition to a lawn or to a garden terrace. The dial plate is of metal as well as the vertical piece upon it, and they may be purchased ready for placing on the pedestal,—the dial with all the hour-lines traced on it, and the style-plate firmly fastened in its proper position, if not even cast in the same piece with the dial-plate.

When placing it on the pedestal care must be taken that the dial be perfectly horizontal and accurately oriented. The levelling will be done with a spirit-level, and the orientation will be best effected either in the forenoon or in the afternoon, by turning the dial-plate till the time given by the shadow (making the one minute correction mentioned above) agrees with a good watch whose error on solar time is known. It is, however, important to bear in mind that a dial, so built up beforehand, will have the angle at the base equal to the latitude of some selected place, such as London, and the hour-lines will be drawn in directions calculated for the same latitude. Such a dial can therefore not be used near Edinburgh or Glasgow, although it would, without appreciable error, be adapted to any place whose latitude did not differ more than 20 or 30 miles from that of London, and it would be safe to employ it in Essex, Kent, or Wiltshire.

If a series of such dials were constructed, differing by 30 miles in latitude, then an intending purchaser could select one adapted to a place whose latitude was within 15 miles of his own, and the error of time would never exceed a small fraction of a minute. The following table will enable us to check the accuracy of the hour-lines and of the angle of the style,—all angles on the dial being readily measured with an ordinary protractor. It extends from 50° lat. to 59½° lat., and therefore includes the whole of Great Britain and Ireland:—

Lat.	XI AM I PM.	X AM II PM.	IX AM III PM.	VIII AM IV PM.	VII AM V PM.	VI AM VI PM.
50° 0'	11° 36'	23° 51'	37° 27'	53° 0'	70° 43'	90 0
50 30	11 41	24 1	37 39	53 12	70 51	90 0
51 0	11 46	24 10	37 51	53 23	70 59	90 0
51 30	11 51	24 19	38 3	53 35	71 6	90 0
52 0	11 55	24 28	38 14	53 46	71 13	90 0
52 30	12 0	24 37	38 25	53 57	71 20	90 0
53 0	12 5	24 45	38 37	54 8	71 27	90 0
53 30	12 9	24 54	38 48	54 19	71 34	90 0
54 0	12 14	25 2	38 58	54 29	71 40	90 0
54 30	12 18	25 10	39 9	54 39	71 47	90 0
55 0	12 23	25 19	39 19	54 49	71 53	90 0
55 30	12 27	25 27	39 30	54 59	71 59	90 0
56 0	12 31	25 35	39 40	55 9	72 5	90 0
56 30	12 36	25 43	39 50	55 18	72 11	90 0
57 0	12 40	25 50	39 59	55 27	72 17	90 0
57 30	12 44	25 58	40 0	55 36	72 22	90 0
58 0	12 48	26 5	40 18	55 45	72 28	90 0
58 30	12 52	26 13	40 27	55 54	72 33	90 0
59 0	12 56	26 20	40 36	56 2	72 39	90 0
59 30	13 0	26 27	45 45	56 11	72 44	90 0

Vertical South Dial—Let us take again our imaginary transparent sphere QZPA (fig. 4), whose axis PEP is parallel to the earth's axis. Let Z be the zenith, and consequently, the great circle QZP the meridian. Through E, the centre of the sphere, draw a vertical plane facing south. This will cut the sphere in the great circle ZMA which, being vertical, will pass through the zenith, and, facing south, will be at right angles to the meridian. Let QMa be the equatorial circle, obtained by drawing a plane through E at right angles to the axis PEP. The lower portion Ep of the axis will be the style, the vertical line EA in

the meridian plane will be the XII o'clock line, and the horizontal line EM¹ will be the VI o'clock line. Now, as in the previous problem, divide the equatorial circle into 24 equal arcs of 15° each, beginning at α , viz., $\alpha\beta$, $\beta\gamma$, $\gamma\delta$, &c.,—each quadrant αM , MQ , &c., containing six,—then through each point of division

Fig. 4.

and through the axis Pp draw a plane cutting the sphere in 24 equidistant great circles. As the sun revolves round the axis the shadow of the axis will successively fall on these circles at intervals of one hour, and if these circles cross the vertical circle ZMA in the points A, B, C, &c., the shadow of the lower portion Ep of the axis will fall on the lines EA, EB, EC, &c., which will therefore be the required hour-lines on the vertical dial, Ep being the style

There is no necessity for going beyond the VI o'clock hour-line on each side of noon; for, in the winter months the sun sets earlier than 6 o'clock, and in the summer months it passes behind the plane of the dial before that time, and is no longer available.

It remains to show how the angles AEB, AEC, &c., may be calculated.

The spherical triangles pAB, pAC, &c., will give us a simple rule. These triangles are all right-angled at A, the side pA, equal to ZP, is the co-latitude of the place, that is, the difference between the latitude and 90°; and the successive angles ApB, ApC, &c. are 15°, 30°, &c., respectively. Then

$$\tan. AB = \tan. 15^\circ \sin. \text{co-latitude};$$

or more simply,

$$\begin{aligned} \tan. AB &= \tan. 15^\circ \cos. \text{latitude}, \\ \tan. AC &= \tan. 30^\circ \cos. \text{latitude}, \\ &\text{\&c., \&c.} \end{aligned}$$

and the arcs AB, AC so found are the measure of the angles AEB, AEC, &c., required.

We shall, as examples, calculate the 1 o'clock hour angle AEB for each of the four places we had already taken in the horizontal dial.

Madras (13° 4' N lat.)	London (51° 30' N lat.)
Log tan. 15° 9.42805	Log tan. 15° 9.42805
Log cos. 13° 4' 9.98861	Log cos. 51° 30' 9.79415
Log tan. 14° 38' 9.41666	Log tan. 9° 28' 9.22220
Edinburgh (55° 57' N lat.)	Hammefest (73° 40' N lat.)
Log tan. 15° 9.42805	Log tan. 15° 9.42805
Log cos. 55° 57' 9.74812	Log cos. 73° 40' 9.44905
Log tan. 8° 32' 9.17617	Log tan. 4° 19' 8.87710

In this case the angles diminish as the latitudes increase, the opposite result to that of the horizontal dial.

Inclining, Reclining, &c., Dials.—We shall not enter into the calculation of these cases. Our imaginary sphere being, as before supposed, constructed with its centre at the centre of the dial, and all the hour-circles traced upon it, the intersection of these hour-circles with the plane of the

dial will determine the hour-lines just as in the previous cases; but the triangles will no longer be right-angled, and the simplicity of the calculation will be lost, the chances of error being greatly increased by the difficulty of drawing the dial-plane in its true position on the sphere, since that true position will have to be found from observations which can be only roughly performed.

In all these cases, and in cases where the dial surface is not a plane, and the hour-lines, consequently, are not straight lines, the only safe practical way is to mark rapidly on the dial a few points (one is sufficient when the dial face is plane) of the shadow at the moment when a good watch shows that the hour has arrived, and afterwards connect these points with the centre by a continuous line. Of course the style must have been accurately fixed in its true position before we begin.

Equatorial Dial.—The name equatorial dial is given to one whose plane is at right angles to the style, and therefore parallel to the equator. It is the simplest of all dials. A circle (fig. 5) divided into 24 equal arcs is placed at right angles to the style, and hour divisions are marked upon it. Then if care be taken that the style point accurately to the pole, and that the noon division coincide with the meridian plane, the shadow of the style will fall on the other divisions, each at its proper time. The divisions must be

Fig. 5

marked on both sides of the dial, because the sun will shine on opposite sides in the summer and in the winter months, changing at each equinox.

To find the Meridian Plane.—We have, so far, assumed the meridian plane to be accurately known; we shall proceed to describe some of the methods by which it may be found.

The mariner's compass may be employed as a first rough approximation. It is well known that the needle of the compass, when free to move horizontally, oscillates upon its pivot and settles in a direction termed the magnetic meridian. This does not coincide with the true north and south line, but the difference between them is generally known with tolerable accuracy, and is called the variation of the compass. The variation differs widely at different parts of the surface of the earth, being now about 20° W. in London, 7° W. in New York, and 17° E. in San Francisco. Nor is the variation at any place stationary, though the change is slow. We said that *now* the variation in London is about 20° W.; in 1837 it was about 24° W.; and there is even a small daily oscillation which takes place about the mean position, but too small to need notice here.

With all these elements of uncertainty, it is obvious that the compass can only give a rough approximation to the position of the meridian, but it will serve to fix the style so that only a small further alteration will be necessary when a more perfect determination has been made.

A very simple practical method is the following:—

Place a table (fig. 6), or other plane surface, in such a position that it may receive the sun's rays both in the morning and in the afternoon. Then carefully level the surface by means of a spirit-level. This must be done very accurately, and the table in that position made perfectly secure, so that there be no danger of its shifting during the day.

Next, suspend a plummet SH from a point S, which must be rigidly fixed. The extremity H, where the plummet just meets the surface, should be somewhere near the

¹ EM is obviously horizontal, since M is the intersection of two great circles ZM, QN, each at right angles to the vertical plane QZP.

between the eye and the fixed plummet. The meridian plane will be secured by placing two permanent marks on the ground, one under each plummet.

This method, by means of the two stars, is only available for the upper transit of *Polaris*; for, at the lower transit, the other star γ *Ursæ Majoris* would pass close to or beyond the zenith, and the observation could not be made. Also the stars will not be visible when the upper transit takes place in the day-time, so that one-half of the year is lost to this method.

Neither could it be employed in lower latitudes than 40° N., for there the star would be below the horizon at its lower transit;—we may even say not lower than 45° N., for the star must be at least 5° above the horizon before it becomes distinctly visible.

There are other pairs of stars which could be similarly employed, but none so convenient as these two, on account of *Polaris* with its very slow motion being one of the pair.

To place the Style in its True Position without previous determination of the Meridian Plane—The various methods given above for finding the meridian plane have for ultimate object the determination of the plane, not on its own account, but as an element for fixing the instant of noon, whereby the style may be properly placed.

We shall dispense, therefore, with all this preliminary work if we determine noon by astronomical observation. For this we shall want a good watch, or pocket chronometer, and a sextant or other instrument for taking altitudes. The local time at any moment may be determined in a variety of ways by observation of the celestial bodies. The simplest and most practically useful methods will be found described and investigated in any good educational work on astronomy.

For our present purpose a single altitude of the sun taken in the forenoon will be most suitable. At some time in the morning, when the sun is high enough to be free from the mists and uncertain refractions of the horizon—but to insure accuracy, while the rate of increase of the altitude is still tolerably rapid, and, therefore, not later than 10 o'clock—take an altitude of the sun, an assistant, at the same moment, marking the time shown by the watch. The altitude so observed being properly corrected for refraction, parallax, &c., will, together with the latitude of the place, and the sun's declination, taken from the *Nautical Almanac*, enable us to calculate the time. This will be the solar or apparent time, that is, the very time we require; and we must carefully abstain from applying the equation of time. Comparing the time so found with the time shown by the watch, we see at once by how much the watch is fast or slow of solar time; we know, therefore, exactly what time the watch must mark when solar noon arrives, and waiting for that instant we can fix the style in its proper position as explained before.

We can dispense with the sextant and with all calculation and observation if, by means of the pocket chronometer, we bring the time from some observatory where the work is done; and, allowing for the change of longitude, and also for the equation of time, if the time we have brought is clock time, we shall have the exact instant of solar noon as in the previous case.

In remote country districts a dial will always be of use to check and even to correct the village clock; and the description and directions here given will, we think, enable any ingenious artisan to construct one.

In former times the fancy of dialists seems to have run riot in devising elaborate surfaces on which the dial was to be traced. Sometimes the shadow was received on a cone, sometimes on a cylinder, or on a sphere, or on a combination of these. A universal dial was constructed of a figure in the shape of a cross; another universal dial

showed the hours by a globe and by several gnomons. These universal dials required adjusting before use, and for this a mariner's compass and a spirit-level were necessary. But it would be tedious and useless to enumerate the various forms designed, and, as a rule, the more complex the less accurate.

Another class of useless dials consisted of those with variable centres. They were drawn on fixed horizontal planes, and each day the style had to be shifted to a new position. Instead of hour-lines they had hour-points; and the style, instead of being parallel to the axis of the earth, might make any chosen angle with the horizon. There was no practical advantage in their use, but rather the reverse; and they can only be considered as furnishing material for new mathematical problems.

Portable Dials—The dials so far described have been fixed dials, for even the fanciful ones to which reference was just now made were to be fixed before using. There were, however, other dials, made generally of a small size, so as to be carried in the pocket; and these, so long as the sun shone, roughly answered the purpose of a watch.

The description of the portable dial has generally been mixed up with that of the fixed dial, as if it had been merely a special case, and the same principle had been the basis of both; whereas there are essential points of difference between them, besides those which are at once apparent.

In the fixed dial the result depends on the *uniform* angular motion of the sun round the fixed style; and a small error in the assumed position of the sun, whether due to the imperfection of the instrument, or to some small neglected correction, has only a trifling effect on the time. This is owing to the angular displacement of the sun being so rapid—a quarter of a degree every minute—that for the ordinary affairs of life greater accuracy is not required, as a displacement of a quarter of a degree, or at any rate of one degree, can be readily seen by nearly every person. But with a portable dial this is no longer the case. The uniform angular motion is not now available, because we have no determined fixed plane to which we may refer it. In the new position, to which the observer has gone, the zenith is the only point of the heavens he can at once practically find; and the basis for the determination of the time is the constantly but *very irregularly* varying zenith distance of the sun.

At sea the observation of the altitude of a celestial body is the only method available for finding local time, but the perfection which has been attained in the construction of the sextant (chiefly by the introduction of telescopes) enables the sailor to reckon on an accuracy of seconds instead of minutes. Certain precautions have, however, to be taken. The observations must not be made within a couple of hours of noon, on account of the slow rate of change at that time, nor too near the horizon, on account of the uncertain refractions there; and the same restrictions must be observed in using a portable dial.

To compare roughly the value (as to accuracy) of the fixed and the portable dials, let us take a mean position in Great Britain, say 54° lat., and a mean declination when the sun is in the equator. It will rise at 6 o'clock, and at noon have an altitude of 36° ,—that is, the portable dial will indicate an average change of one-tenth of a degree in each minute, or two and half times slower than the fixed dial. The vertical motion of the sun increases, however, nearer the horizon, but even there it will be only one-eighth of a degree each minute, or half the rate of the fixed dial, which goes on at nearly the same speed throughout the day.

Portable dials are also much more restricted in the range of latitude for which they are available, and they should

between the eye and the fixed plummet. The meridian plane will be secured by placing two permanent marks on the ground, one under each plummet.

This method, by means of the two stars, is only available for the upper transit of *Polaris*; for, at the lower transit, the other star η *Ursæ Majoris* would pass close to or beyond the zenith, and the observation could not be made. Also the stars will not be visible when the upper transit takes place in the day-time, so that one-half of the year is lost to this method.

Neither could it be employed in lower latitudes than 40° N., for there the star would be below the horizon at its lower transit;—we may even say not lower than 45° N., for the star must be at least 5° above the horizon before it becomes distinctly visible.

There are other pairs of stars which could be similarly employed, but none so convenient as these two, on account of *Polaris* with its very slow motion being one of the pair.

To place the Style in its True Position without previous determination of the Meridian Plane.—The various methods given above for finding the meridian plane have for ultimate object the determination of the plane, not on its own account, but as an element for fixing the instant of noon, whereby the style may be properly placed.

We shall dispense, therefore, with all this preliminary work if we determine noon by astronomical observation. For this we shall want a good watch, or pocket chronometer, and a sextant or other instrument for taking altitudes. The local time at any moment may be determined in a variety of ways by observation of the celestial bodies. The simplest and most practically useful methods will be found described and investigated in any good educational work on astronomy.

The altitude so observed being properly corrected for refraction, parallax, &c., will, together with the latitude of the place, and the sun's declination, taken from the *Nautical Almanac*, enable us to calculate the time. This will be the solar or apparent time, that is, the very time we require; and we must carefully abstain from applying the equation of time. Comparing the time so found with the time shown by the watch, we see at once by how much the watch is fast or slow of solar time; we know, therefore, exactly what time the watch must mark when solar noon arrives, and waiting for that instant we can fix the style in its proper position as explained before.

We can dispense with the sextant and with all calculation and observation if, by means of the pocket chronometer, we bring the time from some observatory where the work is done; and, allowing for the change of longitude, and also for the equation of time, if the time we have brought is clock time, we shall have the exact instant of solar noon as in the previous case.

In remote country districts a dial will always be of use to check and even to correct the village clock, and the description and directions here given will, we think, enable any ingenious artisan to construct one.

In former times the fancy of dialists seems to have run riot in devising elaborate surfaces on which the dial was to be traced. Sometimes the shadow was received on a cone, sometimes on a cylinder, or on a sphere, or on a combination of these. A universal dial was constructed of a figure in the shape of a cross; another universal dial

showed the hours by a globe and by several gnomons. These universal dials required adjusting before use, and for this a mariner's compass and a spirit-level were necessary. But it would be tedious and useless to enumerate the various forms designed, and, as a rule, the more complex the less accurate.

Another class of useless dials consisted of those with variable centres. They were drawn on fixed horizontal planes, and each day the style had to be shifted to a new position. Instead of hour-lines they had hour-points; and the style, instead of being parallel to the axis of the earth, might make any chosen angle with the horizon. There was no practical advantage in their use, but rather the reverse, and they can only be considered as furnishing material for new mathematical problems.

Portable Dials.—The dials so far described have been fixed dials, for even the fanciful ones to which reference was just now made were to be fixed before using. There were, however, other dials, made generally of a small size, so as to be carried in the pocket, and these, so long as the sun shone, roughly answered the purpose of a watch.

The description of the portable dial has generally been mixed up with that of the fixed dial, as if it had been merely a special case, and the same principle had been the basis of both; whereas there are essential points of difference between them, besides those which are at once apparent.

In the fixed dial the result depends on the *uniform* angular motion of the sun round the fixed style, and a small error in the assumed position of the sun, whether due to the imperfection of the instrument, or to some small neglected correction, has only a trifling effect on the time. This is owing to the angular displacement of the sun being so rapid—a quarter of a degree every minute—that for the ordinary affairs of life greater accuracy is not required, as a displacement of a quarter of a degree, or at any rate of one degree, can be readily seen by nearly every person. But with a portable dial this is no longer the case. The uniform angular motion is not now available, because we have no determined fixed plane to which we may refer it. In the new position, to which the observer has gone, the zenith is the only point of the heavens he can at once practically find; and the basis for the determination of the time is the constantly but *very irregularly* varying zenith distance of the sun.

At sea the observation of the altitude of a celestial body is the only method available for finding local time, but the perfection which has been attained in the construction of the sextant (chiefly by the introduction of telescopes) enables the sailor to reckon on an accuracy of seconds instead of minutes. Certain precautions have, however, to be taken. The observations must not be made within a couple of hours of noon, on account of the slow rate of change at that time, nor too near the horizon, on account of the uncertain refractions there; and the same restrictions must be observed in using a portable dial.

To compare roughly the value (as to accuracy) of the fixed and the portable dials, let us take a mean position in Great Britain, say 54° lat., and a mean declination when the sun is in the equator. It will rise at 6 o'clock, and at noon have an altitude of 36° ,—that is, the portable dial will indicate an average change of one-tenth of a degree in each minute, or two and half times slower than the fixed dial. The vertical motion of the sun increases, however, nearer the horizon, but even there it will be only one-eighth of a degree each minute, or half the rate of the fixed dial, which goes on at nearly the same speed throughout the day.

Portable dials are also much more restricted in the range of latitude for which they are available, and they should

not be used more than 4 or 5 miles north or south of the place for which they were constructed.

We shall briefly describe two portable dials which were in actual use

Dial on a Cylinder.—A hollow cylinder of metal (fig 7), 4 or 5 inches high, and about an inch in diameter, has a lid which admits of tolerably easy rotation. A hole in the lid receives the style, shaped somewhat like a bayonet; and the straight part of the style, which, on account of the two bends, is lower than the lid, projects horizontally out from the cylinder to a distance of 1 or $1\frac{1}{2}$ inches. When not in use the style would be taken out and placed inside the cylinder.

A horizontal circle is traced on the cylinder opposite the projecting style, and this circle is divided into 36 approximately equidistant intervals.¹ These intervals represent spaces of time, and to each division is assigned a date, so that each month has three dates marked as follows.—January 10, 20, 31, February 10, 20, 28, March 10, 20, 31, April 10, 20, 30, and so on,—always the 10th, the 20th, and the last day of each month.

Through each point of division a vertical line parallel to the axis of the cylinder is drawn from top to bottom. Now it will be readily understood that if, upon one of these days, the lid be turned so as to bring the style exactly opposite the date, and if the dial be then placed on a horizontal table so as to receive sun-light, and turned round *bodily* until the shadow of the style falls exactly on the vertical line below it, the shadow will terminate at some definite point of this line, the position of which point will depend on the length of the style—that is, the distance of its end from the surface of the cylinder—and on the altitude of the sun at that instant. Suppose that the observations are continued all day, the cylinder being very gradually turned so that the style may always face the sun, and suppose that marks are made on the vertical line to show the extremity of the shadow at each exact hour from sunrise to sunset—these times being taken from a good fixed sun dial,—then it is obvious that the next year, on the *same date*, the sun's declination being about the same, and the observer in about the same latitude, the marks made the previous year will serve to tell the time all that day.

What we have said above was merely to make the principle of the instrument clear, for it is evident that this mode of marking, which would require a whole year's sunshine and hourly observation, cannot be the method employed.

The positions of the marks are, in fact, obtained by calculation. Corresponding to a given date, the declination

of the sun is taken from the almanac, and this, together with the latitude of the place and the length of the style, will constitute the necessary data for computing the length of the shadow, that is, the distance of the mark below the style for each successive hour.

We have assumed above that the declination of the sun is the same at the same date in different years. This is not quite correct, but, if the dates be taken for the second year after leap year, the results will be sufficiently approximate. The actual calculations will offer no difficulty.

When all the hour marks have been placed opposite to their respective dates, then a continuous curve, joining the corresponding hour-points, will serve to find the time for a day intermediate to those set down, the lid being turned till the style occupy a proper position between the two divisions. The horizontality of the surface on which the instrument rests is a very necessary condition, especially in summer, when, the shadow of the style being long, the extreme end will shift rapidly for a small deviation from the vertical, and render the reading uncertain. The dial can also be used by holding it up by a small ring in the top of the lid, and probably the verticality is better ensured in that way.

Portable Dial on a Card.—This neat and very ingenious dial is attributed by Ozanam to a Jesuit Father, *De Saint Rigaud*, and probably dates from the early part of the 17th century. Ozanam says that it was sometimes called the *capuchin*, from some fancied resemblance to a cowl thrown back.

Construction.—Draw a straight line ACB parallel to the top of the card (fig 8) and another DCE at right angles to it; with C as

Fig. 8

¹ Strict equality is not necessary, as the observations made are on the vertical line through each division-point, without reference to the others. It is not even requisite that the divisions should go completely and exactly round the cylinder, although they were always so drawn, and both these conditions were insisted upon in the directions for the construction.

centre, and any convenient radius CA, describe the semi-circle AEB below the horizontal. Divide the whole arc AEB into 12 equal parts at the points *r, s, t, &c.*, and through these points draw perpendiculars to the diameter ACB, these lines will be the hour lines, viz., the line through *r* will be the XI line, the line through *s* the X line, and so on; the hour line of noon will be the point A

itself; by subdivision of the small arcs Ar , rs , st , &c., we may draw the hour lines corresponding to halves and quarters, but this only where it can be done without confusion.

Draw ASD making with AC an angle equal to the latitude of the place, and let it meet EC in D , through which point draw FDG at right angles to AD .

With centre A , and any convenient radius AS , describe an arc of circle RST , and graduate this arc by marking degree divisions on it, extending from 0° at S to $23\frac{1}{2}^\circ$ on each side at R and T . Next determine the points on the straight line FDG where radii drawn from A to the degree divisions on the arc would cross it, and carefully mark these crossings.

The divisions of RST are to correspond to the sun's declination, south declinations on RS and north declinations on ST . In the other hemisphere of the earth this would be reversed, the north declinations would be on the upper half.

Now, taking a second year after leap year (because the declinations of that year are about the mean of each set of four years), find the days of the month when the sun has these different declinations, and place these dates, or so many of them as can be shown without confusion, opposite the corresponding marks on FDG . Draw the *sun-line* at the top of the card parallel to the line ACB ; and, near the extremity, to the right, draw any small figure intended to form, as it were, a door of which $a b$ shall be the hinge. Care must be taken that this hinge is exactly at right angles to the *sun-line*. Make a fine open slit $c d$ right through the card and extending from the hinge to a short distance on the door,—the centre line of this slit coinciding accurately with the *sun-line*. Now, cut the door completely through the card, except, of course, along the hinge, which, when the card is thick, should be partly cut through at the back, to facilitate the opening. Cut the card right through along the line FDG , and pass a thread carrying a little plummet W and a *very* small bead P , the bead having sufficient friction with the thread to retain any position when acted on only by its own weight, but sliding easily along the thread when moved by the hand. At the back of the card the thread terminates in a knot to hinder it from being drawn through, or better, because giving more friction and a better hold, it passes through the centre of a small disc of card—a fraction of an inch in diameter—and, by a knot, is made fast at the back of the disc.

To complete the construction,—with the centres F and G , and radii FA and GA , draw the two arcs AY and AZ which will limit the hour lines, for in an observation the bead will always be found between them. The forenoon and afternoon hours may then be marked as indicated in the figure. The dial does not of itself discriminate between forenoon and afternoon; but extraneous circumstances, as, for instance, whether the sun is rising or falling, will settle that point, except when close to noon, where it will always be uncertain.

To *rectify* the dial (using the old expression, which means to prepare the dial for an observation),—open the small door, by turning it about its hinge, till it stands well out in front. Next, set the thread in the line FG opposite the day of the month, and stretching it over the point A , slide the bead P along till it exactly coincide with A .

To find the hour of the day,—hold the dial in a vertical position in such a way that its plane may pass through the sun. The verticality is ensured by seeing that the bead rests against the card without pressing. Now gradually tilt the dial (without altering its vertical plane), until the central line of sunshine, passing through the open slit of the door, just falls along the *sun-line*. The hour line against which the head P then rests indicates the time.

The *sun-line* drawn above has always, so far as we know, been used as a *shadow-line*. The upper edge of the rectangular door was the prolongation of the line, and, the door being opened, the dial was gradually tilted until the shadow cast by the upper edge exactly coincided with it. But this shadow tilts the card one-quarter of a degree more than the *sun-line*, because it is given by that portion of the sun which just appears above the edge, that is, by the upper limb of the sun, which is one-quarter of a degree higher than the centre. Now, even at some distance from noon, the sun will sometimes take a considerable time to rise one-quarter of a degree, and by so much time will the indication of the dial be in error.

The central line of light which comes through the open slit will be free from this error, because it is given by light from the centre of the sun.

The card-dial deserves to be looked upon as something more than a mere toy. Its ingenuity and scientific accuracy give it an educational value which is not to be measured by the roughness of the results obtained, and the following demonstration of its correctness will, it is hoped, usefully close what we have to say on this subject.

Demonstration.—Let H (fig. 9) be the point of suspension of the plummet at the time of observation, so that the angle DAH is the north declination of the sun,— P , the head, resting against the hour-

line VX . Join CX , then the angle ACX is the hour angle from noon given by the bead, and we have to prove that this hour-angle is the correct one corresponding to a north latitude DAC , a north declination DAH and an altitude equal to the angle which the

Fig. 9.

sun-line, or its parallel AC , makes with the horizontal. The angle PHQ will be equal to the altitude, if HQ be drawn parallel to DC , for the pair of lines HQ, HP will be respectively at right angles to the *sun-line* and the horizontal.

Draw PQ and HM parallel to AC , and let them meet DCE in M and N respectively.

Let HP and its equal HA be represented by a . Then the following values will be readily deduced from the figure—

$$AD = a \cos. decl., DH = a \sin. decl., PQ = a \sin. alt.$$

$$CX = AC = AD \cos. lat. = a \cos. decl. \cos. lat.$$

$$PN = CV = CX \cos. ACX = a \cos. decl. \cos. lat. \cos. ACX.$$

$$NQ = MH = DH \sin. MDH = a \sin. decl. \sin. lat.$$

$$(\because \text{the angle } MDH = DAC = \text{latitude}).$$

And, since

$$PQ = NQ + PN,$$

we have, by simple substitution,

$$a \sin. alt. = a \sin. decl. \sin. lat. + a \cos. decl. \cos. lat. \cos. ACX;$$

or, dividing by a throughout.

$$\sin. alt. = \sin. decl. \sin. lat. + \cos. decl. \cos. lat. \cos. ACX. \quad (\text{At which equation determines the hour angle } ACX \text{ shown by the head})$$

To determine the hour-angle of the sun at the same moment, let

Fig. 10.

fig. 10 represent the celestial sphere, HR the horizon, P the pole, and Z the zenith, and S the sun.

From the spherical triangle PZS, we have
 $\cos. ZS = \cos. PS \cos. ZP + \sin. PS \sin. ZP \cos. ZPS$
 but $ZS = \text{zenith distance} = 90^\circ - \text{altitude}$
 $ZP = 90^\circ - PR = 90^\circ - \text{latitude}$
 $PS = \text{polar distance} = 90^\circ - \text{declination.}$

therefore, by substitution

$\sin. alt = \sin. decl. \sin. lat + \cos. decl. \cos. lat. \cos. ZPS \dots (B)$
 and ZPS is the hour-angle of the sun.

A comparison of the two formulæ (A) and (B) shows that the hour-angle given by the bead will be the same as that given by the sun, and proves the theoretical accuracy of the card-dial. Just at sun-rise or at sun-set, the amount of refraction slightly exceeds half a degree. If, then, a little cross *m* (see fig 8) be made just below the sun-line, at a distance from it which would subtend half a degree at *c*, the time of sunset would be found corrected for refraction, if the central line of light were made to fall on *cm*.

The following list includes the principal writers on dialling whose works have come down to us, and to these we must refer for descriptions of the various constructions,

some simple and direct, others fanciful and intricate, which have been at different times employed —

Ptolemy, *Analemma*, restored by Commandine; Vitruvius, *Architecture*; Sebastian Münster, *Horologographia*; Orontius Fineus, *De Horologis Solaribus*, Mutio Oddi da Urbino, *Horologi Solari*, Dryander, *De Horologiorum Compositione*, Conrad Gesner, *Pandectæ*; Andrew Schoner, *Gnomonica*, F. Commandine, *Horologiorum Descriptio*, Joan. Bapt. Benedictus, *De Gnomonum Usu*; Georgius Schomberg, *Exegesis Fundamentorum Gnomonicorum*; Joan Solomon de Caus, *Horologes Solaires*, Joan Bapt Trolta, *Praxis Horologiorum*; Desargues, *Manière Universelle pour poser l'Essieu*, &c.; Ath. Kircher, *Ars magna Lucis et Umbra*, Hallum, *Explicatio Horologii in Horto Regio Londini*; Joan Bapt Tractatus *Horologiorum*; Clavius, *Gnomonices de Horologiis*.

Also among more modern writers, Deschales, Ozanam, Schottus, Wolfius, Picard, Lahire, Walper, in German, Paterson, Michael, Muller, and among English writers, Foster, Wells, Collins, Leadbetter, Jones, Leybourn, Emerson, and Ferguson. See also Meikle's article in former editions of the present work. (H G)

DIAMANTE. The Italian fresco painter, commonly known as Fra Diamante, was born at Prato about 1400. He was a Carmelite friar, a member of the Florentine community of that order, and was the friend and assistant of the more celebrated Filippo Lippi. The Carmelite convent of Prato which he adorned with many works in fresco has been suppressed, and the buildings have been altered to a degree involving the destruction of the paintings. He was the principal assistant of Fra Filippo in the grand frescoes which may still be seen at the east end of the cathedral of Prato. In the midst of the work he was recalled to Florence by his conventual superior, and a minute of proceedings of the commune of Prato is still extant, in which it is determined to petition the metropolitan of Florence to obtain his return to Prato,—a proof that his share in the work was so important that his recall involved the suspension of it. Subsequently he assisted Fra Filippo in the execution of the frescoes still to be seen in the cathedral of Spoleto, which Fra Diamante completed in 1470 after his master's death in 1469. Fra Filippo left a son ten years old to the care of Diamante, who, having received 200 ducats from the commune of Spoleto, as the balance due for the work done in the cathedral, returned with the child to Florence, and, as Vasari says, bought land for himself with the money, giving but a small portion to the child. The accusation of wrong-doing, however, would depend upon the share of the work executed by Fra Diamante, and the terms of his agreement with Fra Filippo. Fra Diamante must have been nearly seventy when he completed the frescoes at Spoleto, but the exact year of his death is not known.

See *Relazione delle Pitture di Fra Filippo nel coro di Prato*, by the Canon Baldanzi, Prato, also the last edition of Vasari, Florence, 1543

DIAMANTINA, formerly Tejuco, a town of Brazil, in the province of Minas-Geraes, is situated at an altitude of 5700 feet above sea-level, in a valley watered by affluents of the Jequitinhonha. Its streets are broad, and the houses are mostly of wood. The public structures include several churches, a theatre, barracks, three hospitals, and a school. The surrounding district is sterile, but is rich in minerals. The discovery of diamonds there was made in 1729. Population about 7000, or, with that of the neighbouring villages, 15,000. See BRAZIL, vol. iv. p. 224.

DIAMANTINO, a town of Brazil, in the province of Matto-Grosso, is situated close to the Diamantino river, about six miles from its junction with the Paraguay, at the foot of a high range of country, in $14^\circ 24' 33''$ S lat. and $56^\circ 8' 30''$ W. long. The neighbourhood, which is infertile, yields diamonds and gold. Population about 5000.

DIAMOND. This gem, the most highly valued and history brilliant of precious stones, is also remarkable for its history and its peculiar physical and chemical properties. Though not always accurately distinguished from other similar stones, it seems to have attracted notice at a very early period, especially in India, the chief source of supply in ancient times. The old Jewish doctors regarded the jahalom, the third in the second row of stones in the breast-plate of the high priest (Exod. xxxix. 11), as the diamond, and it is thus translated in the English and other versions. But as each stone bore the name of one of the tribes, and there is no reason to believe that any method of polishing such hard stones, still less of engraving letters on them, was then known, the identification cannot be accurate. Among the Greeks it is first mentioned about three centuries B.C. under the name of *adamas* (ἀδάμας), "the unsubduable," referring to its hardness and power of resisting fire. The same name was previously given to a metal highly valued from its extreme hardness for armour and weapons, and the twofold use of the term continued long both in Greek and Latin. The name of the gem in our own and most modern languages is derived from this old name, occurring in the form *diamas* in Albertus Magnus and other authors of the 13th century. Curiously enough, the French *amant*, applied to the magnet, comes from the same term in its other signification of an ore or metal.

The fullest account of the *adamas* as a stone is found in Pliny, who says it exceeds in value all human things, and its use was confined to kings, and to few even of them. He mentions six varieties, the most remarkable being the Indian and Arabian, of such unspeakable hardness that when struck with a hammer even the iron and anvil were torn asunder—"ita respientes ictum, ut ferrum utrinque dissulset, incudesque etiam ipsi dissiliant." It also resisted the fire, and could only be subdued and broken down when dipped in fresh warm goat's blood. Similar fables continued to prevail during the Middle Ages, and even yet have hardly vanished from popular belief. As an ornamental stone it was highly esteemed during the early times of the Roman empire, as some scandalous stories recorded by Juvenal testify, though only stones with naturally polished faces could be used. This fact is proved not only by the words of Seneca—"nec secari adamas aut credi vel deteri potest"—and others, but from specimens of diamonds set in gold, with no artificial polishing, which have come down both from classic times and from the Middle Ages. This unworkable character long greatly limited both its use and its value; and the more highly coloured rubies, and even emeralds and sapphires, were often preferred to it. It was only after Ludwig van Berghen (or Berghem, as he is often named) in 1476 discovered the mode of cutting and polish-

ing it, that the diamond slowly regained the first place among gems. Even in the 16th century (1550), Benvenuto Cellini (*Trattato dell' orificerio*, cap. i.) assigns it only the third rank in value, estimating a perfect ruby of one carat weight as worth 800 scudi d'oro (each equal to about 4s.), a similar emerald at 400, an equal diamond at 100, and a sapphire at 10 scudi. In the same century the use of the diamond for cutting glass and engraving gems seems also to have become known.

The diamond always occurs in crystals of the tesseral or cubical system. Its most frequent forms are the octahedron, or double four-sided pyramid (fig 1), the rhombic dodecahedron with twelve faces (fig. 2), and others with twenty-four (fig 3), and forty-eight faces

FIG. 1.—The Octahedron.

FIG. 2.—Rhombic Dodecahedron.

FIG. 3.—Triakis octahedron

FIG. 4.—Hexakis octahedron.

(fig. 4). The first form is most common in stones from India, the second in those from Brazil. Cubes also occur, but are rare, whilst the icositetrahedron has not been observed. Hitherto the diamond has been described as hemihedric, but Sadebeck from his own and G. Rose's researches shows it to be holohedric (in the *Berlin Monatsberichte*, Oct. 1876). The faces are often curved, strongly striated, or marked by stair-like inequalities, hiding the true form. Many of the crystals also are round almost like spheres (fig. 5), or the smaller ones like grains of sand. This does not arise, however, from attrition during transport by water, but is the original shape of the stones. Macles, or twin-crystals, specially of two octahedrons, are common, and the striae due to this structure appear even on the polished facets. The diamond has a perfect cleavage parallel to the faces of the octahedron, and breaks readily both in this and other directions. Contrary to the old and still common opinion, it is rather brittle, and is easily injured by a slight blow or fall. Its hardness—10 in the mineralogical scale—far surpasses that of all other known stones, and was used even by the ancients to discriminate it from other gems. In specific gravity, 3.52 (or 3.515 to 3.525), it is considerably higher than rock crystal, but nearly the same as the topaz, which may thus be mistaken for it. According to Fizeau, it has its greatest density at $-42^{\circ}3$ C., and below this begins to expand, a property seen in very few other solid bodies. Its

Fig 5

expansion by heat is very small, the volume from the freezing to the boiling point of water only rising from 1.0 to 1.00000354. By friction it becomes positive electric. The so-called compact diamond or carbonado of the stone polishers, found as round grains or masses of one or two pounds weight in the washings near Bahia, of a brownish black colour and sp. g. = 3.012 to 3.416, is porous diamond mixed with a small amount of other matter.

The optical properties of the diamond are also very remarkable. The purest stones, or those of the first proof water are highly transparent and colourless. But more generally it is less transparent, and shows various tints, specially white, grey, or brown, more rarely blue, red, yellow, green; and very seldom black. Such stones, when the colours are pure, are often highly valued. It is also distinguished by its brilliant adamantine lustre. Newton, two centuries ago, remarked its high refractive power, and from this conjectured that it was a substance of a peculiar nature. The index of refraction is 2.4135 for the red rays, 2.4195 for the yellow, and 2.4278 for the green. This high refractive power, and the strong reflection at both surfaces, render it seldom completely transparent, but give it the high lustre for which it is valued as an ornament. They also produce the numerous internal reflections seen in the interior of cut stones, all the rays of light falling on the posterior surfaces at angles above 25° being totally reflected. Like all crystals of the same system it possesses only simple refraction, but Dr (Sir David) Brewster found that many showed traces of double refraction by their action on polarized light. This he ascribed to a peculiar tension produced in the interior of the stone during its formation, and a somewhat similar explanation is still adopted.

In a history of gems published early in the 17th century, Boetius de Boot conjectured that the diamond was an inflammable body. Robert Boyle, who in 1664 described its property of shining in the dark, or phosphorescing after being exposed to the light of the sun, a few years later observed that a part of it was dissipated in acrid vapours when subjected to a high temperature. This combustibility of the diamond was confirmed in 1694 and 1695 by experiments with a powerful burning glass or lens made in the presence of Cosmo III., grand duke of Tuscany, by the Florentine Academicians. The experiment of the combustibility of the diamond when freely exposed in a strong heat has been often repeated, and its true character was proved by Lavoisier, who determined that the product was carbonic acid gas. Sir George Mackenzie converted iron into steel by powdered diamonds; whilst Mr Smithson Tennant showed that the carbonic acid produced corresponded to the oxygen consumed. No doubt, therefore, now remains that the diamond is only pure carbon in the crystallized condition, and like it insoluble in acids.

In regard to the action of heat on the diamond, various experiments have been made. Before the blowpipe it is infusible, and closely packed in powdered charcoal it can resist a very high temperature. But when oxygen is present it burns slowly at a temperature usually given at about that of melting silver. Gustaf Rose lately found that when air is excluded diamonds exposed to a temperature at which pig-iron melts, or to the strongest heat produced in the porcelain kiln, undergo no change; but at a higher temperature, like that at which bar-iron melts, they begin, whilst retaining their form, to be converted into graphite. He further observed that when diamonds and graphite were exposed together in the same muffle, foliated graphite was far more difficult to burn than the diamond, but compact graphite was consumed more readily. In the current of air the diamond gradually became smaller and smaller, but retaining its brilliancy till it finally vanished.

The faces also during burning became marked with peculiar triangular hollows, with their sides parallel to the edges of the octahedron. Seen in a strong light they appear as faces of an icositetrahedron, whilst other regular triangular impressions on the faces of natural crystals of diamond are produced by faces of the dodecahedron. (Rose, "Ueber das Verhalten des Diamants," &c, in Berlin *Monatsberichte*, June 1872)

India is the oldest, and was long the most celebrated, or rather the only, source of diamonds. They have been obtained from a wide district on the eastern side of the Deccan, extending from the Pennar river in 14° N. lat. to near the Sone, in Bundelkund, in 25° N. lat. In the south the chief mines were at Cuddapah, Karnul, and Ellore, near the Krishna, in Madras presidency. In this district some of the largest Indian diamonds were obtained, Golconda, however, not being a mine, but a fortress where the diamonds were collected. There were other mines near Nagpore, and east at Sambhalpur, on the Mahanuddy, and north at Panna, in Bundelkund. At all of these the diamond was sought chiefly in recent deposits, beds of sand and clay, or in some places a ferruginous sandstone or conglomerate, but probably none of them the original matrix. Heyne states that the diamond has hitherto been found only in alluvial soil, or in the most recent rocks; and that the stones are not scattered through the whole of these beds, but confined to one rather harder than the rest. The upper stratum, of 18 inches, consists of sand, gravel, and loam; next there is a deposit of stiff black clay or mud, about 4 feet thick; and next the diamond bed, which is distinguished by a mixture of large rounded stones. It is from 2 to 2½ feet thick, closely cemented together with clay. Sometimes this stratum is covered with calcareous tufa. Here shallow pits are excavated, of a few feet in diameter, in such spots as the practice of the workman may induce him to select; he sinks to a depth of a few feet, and searches the bed which he considers most promising for his purposes; and if he meets with little encouragement, he shifts his situation and proceeds elsewhere. Thus a great deal of the country may be turned to waste and neglected. The working was chiefly in the hands of certain tribes or castes, but was conducted on no regular plan, and afforded a very miserable livelihood. There has been little change since, and though mines still exist at Panna, Karnul, and a few other places, but comparatively few diamonds are found, and probably scarcely pay the expense of collecting them. Diamonds have also been long collected in Borneo, at Pontiana, near the south-east extremity of the island. They occur in a red clay along with gold and platina, and the rajah of Mattan is said to possess one weighing 367 carats, of the purest water, but uncut.

During the end of last and the beginning of the present century the supply of diamonds chiefly came from Brazil. They were first recognized in 1727 in the province of Minas Geraes, where they had been long used by the negroes as counters in playing cards. The principal mines are still in that province near Diamantina (formerly Tejuco), and near Diamantino in Matto Grosso. Mines have also been recently worked in the province of Bahia. Other localities are enumerated in the article BRAZIL. The diamonds are chiefly obtained from the Cascalho, a loose, gravelly deposit mixed with red clay, and containing large lumps of quartz and grains of gold. This rock is probably derived from the itacolumite, a quartzose variety of mica slate, or metamorphosed sandstone, on which it often rests, and in which diamonds are also said to occur. When first brought to Europe the Brazil diamonds were regarded as inferior to those from India, but without reason. Though the mines are strictly watched

as Crown property, the produce is not well ascertained. Martius estimated that in the forty-six years from 1772 to 1818 diamonds weighing about 3,000,000 carats, and worth £7,000,000, were exported. Mr Mawe stated the produce at 25,000 to 30,000 carats annually of rough diamonds, equal to 8000 or 9000 carats when reduced to brilliants. After his time it seems to have greatly decreased, the whole value from 1861 to 1867 being given at about £1,900,000; and the discovery of the Cape diamonds has further reduced the amount. The stones are mostly small, averaging little more than one carat, and very rarely exceeding twenty carats. The largest diamond from Brazil was long an uncut octahedron of 120 carats, but in 1854 a fine stone of 254½ carats was sent to London. It was an irregular dodecahedron, but of brilliant lustre and with no flaws. Since cut it weighs about 124 carats, and is known as the "Star of the South."

Diamonds occur in other parts of America, having been found in the Sierra Madre, south-west of Acapulco in Mexico; and a few also in Georgia and North Carolina. They have also been obtained in California, but all small (under 2 carats); and in the district of Arizona, where one is mentioned of 3 carats.

In 1829 diamonds were discovered on the European side of the Ural mountains in the gold washings near the iron mines of Bissersk. Engelhardt conjectured that they were derived from a dolomitic rock, but others state that it is mica slate like that of Brazil. Only about seventy were found in the first twenty years, and all of them small, the largest weighing under 8 carats. The only other European locality is at Blaschkowitz, in Bohemia, where a single diamond was found in the sand containing pyropes,—the one said by Murray to have been picked up in a brook in Ireland being very doubtful.

Not more important are those from Australia, where they were found as early as 1852, and again in 1859, on the Macquarie river. In 1869 they were discovered in the Mudgee, near one of the tributaries of the Macquarie, by gold-diggers, and worked for a time pretty extensively. They lie there in old river drift covered by basalt said to be of Pliocene age. They occur in a similar position in the Bingera diamond field. In both places they are sparingly distributed and small, the largest mentioned being under 6 carats.

Far more important are the diamond fields of South Africa. In 1867 a Dutch farmer obtained from a boer a bright stone which his children were using as a plaything. This stone was sent to the Cape, where its true nature as a diamond was recognized, and subsequently forwarded to the Paris exhibition and sold for £500. This valuable discovery soon led to further researches, and diamonds were obtained from various places near the Orange and Vaal rivers in Griqua Land West. They were first collected by washing recent alluvial or supposed lacustrine deposits, apparently the detritus of rocks in the vicinity, that are spread over the lower river valleys, but are now rather sought for in "pans," or "pipes," of a circular form running down into the inferior strata, or shale, and filled with a peculiar igneous rock, named diabase, or gabbro, often much changed near the surface. Throughout this rock, which has been penetrated to a depth of from 100 to 200 feet, diamonds are disseminated weighing from over 150 carats down to the 100th of a carat, or less. Many are entire, well-formed crystals, but a large proportion are broken and isolated fragments. Hence it has been inferred that the rock in which they now occur is not the matrix or mother rock in which they were originally formed, but that the "pipes" are rather channels by which volcanic matter has made its way to the surface, bringing the diamonds along with it from some inferior deposit. However this may be,

diamond-digging has become a regular branch of industry to a large population; and it is probable, though no very accurate estimate can be formed, that nearly fifteen million pounds sterling worth of diamonds have been obtained from this district since their discovery. The largest diamond from the Cape we have seen mentioned is the Stewart, of 288 $\frac{3}{4}$ carats, found on the Vaal river in 1872. It was an irregular octahedron of the purest water, and $1\frac{1}{4}$ inch in diameter, and is of a light yellow since cut.

Origin. There has been much speculation regarding the mode of origin of these gems, but hitherto leading to no certain result. Newton conjectured that the diamond was "an unctuous substance coagulated;" Jameson thought it might be a secretion from some ancient tree, like amber, and Brewster also traced it to a vegetable source. Lavoisier, Guyton-Morveau, and others observed black specks when diamonds were burned, which were considered as uncrystallized carbon. Petzhold, in 1842, also supported this view, affirming that he had found vegetable cells in the ashes of diamonds. Goeppert, in his Haarlem Prize Essay, in 1863, supported the same view, both from supposed plant tissues and from other inclusions in diamonds, but admitted that the evidence was not free from doubts. Liebig and others have explained its origin by a slow process of decomposition in a fluid rich in carbon and hydrogen. On the other hand, the occurrence of the diamond in the itacolumite or mica slate, and more recently in or near igneous rocks, as at the Cape, has tended to favour the view that it owes its origin to heat or metamorphic action, as is the case with graphite. But this, as graphite also shows, does not preclude the idea that originally it may have been, like amber, some peculiar vegetable product, subsequently altered and crystallized. It may here also be mentioned that all attempts to produce diamonds artificially have hitherto failed.

Use. Diamonds are chiefly used and valued as ornamental stones, and for this purpose they are cut in various forms according to the original shape of the crystals. It is probable that the Indians knew some method of doing this at an early period, and it is said there were diamond-polishers in Nuremberg even in 1373. Berghem of Bruges has the credit of having first used, in 1456, their own powder for this purpose. He found that by rubbing two diamonds on each other their surfaces were polished and facets formed, and acting on this hint, he employed diamond powder and a polishing wheel. His countrymen continued to follow out the art with great success, but some two centuries ago the English cutters were the more celebrated. The trade then reverted to Holland, but is again returning to Britain, where many of the finest stones are cut. The method has undergone little change, and is still chiefly effected by the hand, partly by rubbing one stone on another, partly by a wheel and diamond powder. Where there are flaws or large pieces of value to be removed, they are occasionally cut by iron wires armed with the powder, or split by a blow of a hammer and chisel in the direction of the natural cleavage. The latter is, however, a dangerous process, as the diamond is very brittle, and many valuable gems have been thus destroyed. When reduced to a proper form, the facets are polished on a lapidary's wheel. The process demands not only great skill but much time and labour. The period required to reduce a stone of 24 or 30 carats to a regular form extended formerly to at least seven or eight months of constant work, and in the case of the Pitt diamond two years were needed; but the time is now greatly shortened by the use of machinery driven by steam. Jewellers have long cut diamonds in three forms—the brilliant, the rose, and tables. The *brilliant* is most esteemed, as giving highest effect

to the lustre, and implying less reduction of the stone. It is, as it were, a modification of the primary octahedron, the most common form of crystal, and is shown in its first form in figs 6 and 7, and with the full number

Fig. 6.

Fig. 8.

Fig. 7.

Fig. 9.

Figs 6-9—Showing cutting of brilliants.

of facets in figs. 8 and 9. Figs 4 and 6 show the upper surfaces, with the *table*, or principal face, in the middle, surrounded by the *bezel*, or upper faces, lying between its edge and the *girdle*, or common base of the two pyramids. The lower facet corresponding to the table is named the *collet*, and the whole portion below the girdle the *collet side*. The portion removed to form the table (generally $\frac{1}{15}$ th) and the collet ($\frac{1}{18}$ th) is shown in fig. 10.

Brilliant are usually set open, both the upper or table side and the lower collet-side being exposed. The *rose cut* (upper view, fig 11; lateral view, fig 12) is given to stones which have too little depth to be cut as brilliants, it has the whole upper curved surface covered with equilateral triangles.

Fig. 10.

The *table diamond*, figs. 13 and 14, the least beautiful, is adopted for broad stones of trifling depth,

Fig. 11.

Fig. 12.

Figs. 11 and 12—Rose cut.

showing a series of four-sided facets above and below the girdle. Recently brilliants are cut in the *star* form

Fig. 13.

Fig. 14.

Figs. 13 and 14.—Table diamond.

(*taille à étoile*), with the table above only one-fourth the diameter, and thus with less loss of weight. There

nearly the form and size given by Tavernier, and the Koh-i-noor would then surpass all known diamonds in its magnitude as in its eventful history.

It is not necessary to notice in detail other diamonds of smaller size, as the Saney, of $53\frac{1}{2}$ carats, once the property of Charles the Bold, like the Austrian, and afterwards of Louis XIV. of France, but sold in 1830 for £20,000 to the emperor of Russia. In the Russian treasury are also the Shah of 86 carats, and the Polar Star of 40. Other noted ones are the Nassac of $89\frac{3}{4}$ carats (now recut, and $78\frac{5}{8}$), the Piggot of $82\frac{1}{4}$, and the Pasha of Egypt of 40 carats, which cost £28,000. Some are valued for other properties, as the Hope diamond, of a rare colour, a fine blue, and high brilliancy, estimated at £25,000, though only weighing $44\frac{1}{4}$ carats. Red diamonds seem very rare, but there is a brilliant of 10 carats among the crown jewels of Russia, which cost £15,000, and in Dresden some very fine yellow stones, the largest of $29\frac{1}{2}$ carats.

Perhaps even more important is the use of the diamond for cutting glass, for polishing gems and other hard bodies, and recently by engineers for boring machines used in forming tunnels and artesian wells. The glaziers' diamond is about the size of a pin's head, and is set in copper or brass. The curvature of the fracture faces gives a sharp edge that cuts and not scratches merely. Each costs about 12s. to 18s., and, as it will weigh only about $\frac{1}{100}$ th carat, the price is higher than that used as gems. For polishing purposes the so-called "bort," i. e. stones so imperfect in form and quality as to be useless for ornament, are broken down and crushed into diamond powder. The carbonado from Bahia is also employed both for polishing and for boring machines. In the latter the stones are fixed in a ring of steel, made to revolve with great rapidity, and kept cool by a current of water, which also removes the detritus. In consequence its price has risen lately from about 1s. to 18s. or 20s. a carat.

The literature of the diamond is very extensive, and scattered through many works. Its history in ancient times is given by Punder, *De Adamante*, Berlin, 1829; its general character in treatises on mineralogy and on precious stones—of the latter those by Jeffries, London, 1757; Mawe, ib 1831; Emanuel, ib 1865, and Streeter, ib 1877, with the *Edelsteinkunde* of Klügel, Leipzig, 1860, and of Schrauf, Vienna, 1869, may be mentioned. More special are Murray, *Memoir on the Diamond*, London, 1831; Petzholdt, *Beiträge zur Natur d. Diamanten*, Dresden, 1842; Goepfert, *Ueber Einschlüsse in D.*, Haarlem, 1864; and many papers in the journals and transactions of scientific societies. For its mode of occurrence may be consulted.—in India, Heyne's *Tracts*, London, 1814; Ritter's *Erdkunde*, Aven, vol. iv, and many papers by Voysey, Adam, Franklin, Blandford, and others; in Brazil, Mawe's *Travels*, London, 1812; Eschwege, Claussen, Spix and Martius, Gardner, Tschudi, &c., for the Ural, Rose's *Reise*, vol. 1, but with much general information; for Australia, Liversidge, in *Jour. Geol. Society*, for the Cape, many papers in the *Journals of Geol. Society* and the *Society of Arts*, and in the *Geological Magazine*, by R. Jones, Tennant, Dunn, Maskelyne, Flight, and Stow; and by Cohen in Leonhard and Gemetz's *Jahrbuch* (J. NI.)

DIANA, who was at a later period revered as the Greek Artemis by the side of Apollo, was originally an independent deity of Italy, as, indeed, is shown by the name, which is the feminine form of Janus. She is essentially the moon goddess, and presides over wood, plain, and water, as well as over the changes of human character, and the special functions of the female sex, also over chase and war. Diana was worshipped by the Sabines, but more especially by the Æqui, Hernici, and Latins, whose united sanctuary lay in the wooded hills of Algidus beyond Tusculum. Diana had also a sanctuary in Anagnina, the capital of the Hernici, and another in Corne, near Tusculum. But more celebrated than all these was the grove and sanctuary of Diana of Aricia, on the Lake of Nemi, which gave the name of *Nemorensis* to Diana. Here she was worshipped side by side with a male deity

Virbius. After the destruction of Alba Longa this grove was for a long time the united sanctuary of the neighbouring Latin and Rutulian cities, until at last it was extinguished beneath the supremacy of Rome. The festival of the goddess was on the ides of August, the full moon of the hot season. She was worshipped with torches, her aid was sought by women seeking a happy deliverance in childbirth, and many votive offerings have rewarded modern excavations on the site. Another celebrated sanctuary of Diana was that on the slopes of Mount Tifata, near Capua, where she was worshipped under the name of Tifatina. This sanctuary was specially favoured by Sulla and at a later period by Vespasian. There were several ancient groves and sanctuaries of Diana in Rome, one in the Vicus Patricius between the Viminal and Esquiline, into which no man was admitted, another at the highest point of the Vicus Cyprius, another on the Cœliolus. But the most celebrated of all was the temple on the Aventine. This was originally a sanctuary of the Latin League, which accounts for the hill not being included in the original circuit of Rome, and for its being the refuge of the plebeians in political disturbances. The statue of the goddess was of the Ephesian type, the day of dedication was the ides of August, and the temple was especially frequented by slaves and their wives. Runaway slaves throughout Italy had a special dependence upon Diana. Such are the chief characteristics of the Roman Diana, but as early as 400 B.C. she began to be identified with the Greek Artemis, of which an account has already been given (see ARTEMIS). For fuller information see Preller, *Römische Mythologie*.

DIANO, or TEGGIANO, a town of Italy in the province of Principato Citeriore, 45 miles south-east of Salerno, on an isolated eminence, above the upper part of the valley of the Negro, or *Tanager*, to which it gives the name of Val di Diano. It represents the ancient Teganum, a municipal town of Lucania, of which the ruins can still be traced at the foot of the hill, and it possesses a castle, several churches of some interest, and three conventual buildings. In 1497 it was strong enough to resist, under Antonio Sanseverino of Salerno, the siege undertaken by Frederick of Aragon. Population in 1871, 6224.

DIAPHORETICS (from *διαφορέω*, to carry through), such remedies as promote perspiration. In health there is constantly taking place an exhalation of watery vapour from the skin, by which not only are many of the effete products of nutrition eliminated, but the body is kept cool. Under exertion or in a heated atmosphere this natural function of the skin is increased, sweating more or less profuse follows, and, evaporation going on rapidly over the whole surface, little or no rise in the temperature of the body takes place. In many forms of disease, such as fevers and inflammatory affections, the action of the skin is arrested, and the surface of the body feels harsh and dry, while the temperature is greatly elevated. The occurrence of perspiration not unfrequently marks a crisis in such diseases, and is in general regarded as a favourable event. In some chronic diseases, such as diabetes and some cases of Bright's disease, the absence of perspiration is a marked feature; while, on the other hand, in many wasting diseases, such as phthisis, the action of the skin is increased, and copious exhausting sweating occurs. Many means can be used to induce perspiration, among the best known being baths, either in the form of hot vapour or hot water baths, or in that part of the process of the Turkish bath which consists in exposing the body to a dry and hot atmosphere. Such measures, particularly if followed by the drinking of hot liquids and the wrapping of the body in warm clothing, seldom fail to excite copious perspiration. Numerous medicinal substances have a similar effect, although the *modus operandi*

appears to differ in the case of several of them. Thus antimony and ipecacuan appear to produce their diaphoretic action by their nauseating and depressing or relaxing effects; while others seem to act as direct stimulants to the function of the sudoriparous glands of the skin, such as the well-known diaphoretics—Mindererus spirit (acetate of ammonia), guaiacum, nitrous ether, and the recently introduced drug, jaborandi. Opium acts powerfully as a diaphoretic, especially when in combination with ipecacuan, as in Dover's powder, or with antimony, and alcohol has similar properties. Diaphoretics are of great service in many diseases. When employed at the commencement of a catarrh or common cold they frequently check it, and thus prevent the evils which are so apt to follow this affection. In acute dropsy due to kidney disease, such as that which sometimes results from scarlet fever, the hot air or hot water bath is a valuable remedy, and even in dropsical accumulations of long standing, when diaphoresis can be induced, marked improvement in the symptoms generally follows. In certain circumstances, however, diaphoretics, particularly in the form of baths, may be unsafe, especially where there is any affection of the heart or lungs attended with embarrassed respiration; and in general in diseases where diaphoretics seem to be indicated, the physician is required to take into account the patient's whole condition in his selection of any one remedy for this purpose.

DIARBEKIR (or *Kara Amid*, the Black Amid), a city of Asiatic Turkey, the administrative centre of the pashalic of the same name, is situated 2050 feet above the level of the sea, on a mass of basaltic rock which rises abruptly to a height of 100 feet from the western bank of the Tigris, about 100 miles north-east of Aleppo, in $37^{\circ} 55' 50''$ N. lat. and $39^{\circ} 53' 39''$ E. long. It is about three miles in circumference, has a nearly circular form, and is encompassed by ancient and dilapidated walls of a very remarkable character. They are built of basalt, have in most places a thickness of 14 feet, vary in height from 30 to 40 or 50 feet, and are strengthened by upwards of 70 towers, some square and some round, which communicate with each other by two passages formed in the heart of the masonry. There are four gates, which are closed at night:—the Dagh Kapi, or Mountain gate, on the N.; the Rum Kapi, or Anatolian gate, on the W.; the Mardin gate on the S.; and on the E. the Kyöprü gate, which takes its name from the stone bridge that spans the Tigris. Both the gates and the walls bear numerous ornamental designs and inscriptions in Arabic and Cufic characters relating to their erection or restoration. The citadel, or *Ich Kaleh*, which stands in the north-east corner between the Dagh Kapi and the Kyöprü Kapi, commands the town; and a fine view of the valley of the Tigris is obtained from one of its towers, supposed to be the belfry of an ancient Christian church. Within the enceinte is the official residence of the pasha, but he has another mansion at some distance from the town in the vicinity of the military barracks. The interior of the town contrasts unfavourably with the massive and spacious character of its defences; it has only one street about 20 feet in breadth, the rest being mere lanes from 4 to 5 feet across. The houses are built of basalt in the lower stories and of dark-coloured brick above; and this, combined with the flat terraces of the roofs, gives a sameness and gloominess of aspect. The public buildings comprise upwards of 50 mosques large and small, 9 Christian churches, a Jewish synagogue, upwards of 20 baths, about 15 khans or caravanserais, and a good military hospital; but only a few are worthy of individual notice, though some of the minarets are richly sculptured, and several of the mosques preserve interesting traces of ancient work. The Ulu-jami, or Great Mosque, which was formerly a Christian church, and perhaps originally the ancient

palace of Tigranes, has an outer wall with two façades, each formed by a row of Corinthian columns surmounted by an equal number of a Byzantine type; the interior is divided into three portions, appropriated to as many Mahometan sects. The Hassan Pasha Khan, in the immediate vicinity of the mosque, is a fine building constructed of layers of white and black stone; but it is exceeded in size by the Ali Pasha Khan, which indeed is the largest in Asiatic Turkey. The town is supplied with water both by springs within the walls and by an aqueduct fed by a fountain at Ali-pinar about two miles to the west; but in the heats of summer, which are sometimes exceedingly severe, these supplies become greatly exhausted and the water impure. In the last century Diarbekir was one of the largest and most flourishing cities of Asia; and as a commercial centre it still ranks second to Mosul, in the upper region of the Tigris and Euphrates. The principal trade routes are by Argana and Kharpot to Samsun, by Sort, Bitlis, and Van, to Tabriz, by Mardin to Mosul, by Urfa and Amtab to Aleppo, and by means of Lalleks, or inflated skins, down the river to Mosul and Baghdad. The bazaars are not much behind those of Baghdad, and display a rich variety of both Asiatic and European wares. Owing partly to the introduction of the latter, the manufacturing industry of the town has greatly decreased, and most of the 1600 cotton looms of which it could boast in 1816 have disappeared. Red and yellow morocco of the greatest repute throughout Asiatic Turkey is still produced, as well as copper vessels, pipe-heads, and goldsmith-work. The population, which was reckoned at 400,000 in 1750, was in the latter part of the century greatly reduced by war, and famine, and pestilence. In 1837 it was estimated by Southgate at from 13,000 to 14,000 souls; in 1856 it was found to be 27,436; and in 1873 it was stated by Cernik at 40,000, and by another authority at 60,000. The principal nationalities in the polyglot community are the Kurds and Armenians, but there are also numerous Turkomans, Turks, and exiled Bulgarians. The Mahometans and Christians are now pretty equally balanced in numbers. Besides representatives of the Armenian, Syrian, and Greek churches, there are Roman Catholics enough to support a church and convent, and a mission is maintained by American Protestants.

Diarbekir is the city which, under the name of Amid, became a Roman colony in 230 A. D. and received a Christian bishop in 325. Fortified by Constantine II. it was before long captured by Sapor the Persian king, after a siege of which a detailed account from his personal experience is given by Ammianus Marcellinus; and in the later wars between the Persians and the Romans it more than once changed hands. On its capture by the former in 562, it is said that 80,000 of its inhabitants perished. After having been from about the 11th century in the possession, by no means uninterrupted, of several Turkoman dynasties, it was finally captured by Selim, the first Sultan of the Osmanli Turks, in the year 1515, and since that date it has remained under the Ottoman rule.

See Sandreczy, *Reise nach Mosul und durch Kurdistan nach Urumia*, 1857; R. J. Gardien's "Description of Diarbekir," in *Journal of Roy. Geogr. Soc.*, 1867; and Cernik, *Technische Studien Expedition durch die Gebiete des Euphrat und Tigris*, 1875.

DIARRHOEA (from *diá*, through, *háo*, to flow), looseness of the bowels. The causes of this complaint are very numerous. As a primary affection it has been treated of under CHOLERA (q. v.) It is frequently a symptom or complication of other diseases, such as consumption or typhoid fever, and as such it will be mentioned in describing the various ailments in which it occurs.

DIAS, ANTONIO GONÇALVES (1823–1861), a Brazilian poet and historian, was born at the little town of Caxias, in Maranhão, with the charms of which he has made his readers familiar. From the university of Coimbra, in Portugal, he returned to his native country well-equipped with legal lore, and obtained an official appointment at Maranhão; but the literary tendency which was strong

within him led him to try his fortune as an author at Rio de Janeiro. Here he wrote for the newspaper press, ventured to appear as a dramatist, and at last in 1846 established his reputation by a volume of poems—*Primieros Cantos*—which appealed to the national feelings of his Brazilian readers, were remarkable for their autobiographic impress, and by their beauty of expression and rhythm placed their author at the head of the lyric poets of his country. In 1848 he followed up his success by *Segundos Cantos e sex Tilhas de Frei Antônio*, in which, as the title indicates, he puts a number of the pieces in the mouth of a simple old Dominican friar, and in the following year, in fulfilment of the duties of his new post as professor of Brazilian history in the imperial college of Pedro II., he published an edition of Berredo, and added a sketch of the migrations of the Indian tribes. A third volume of poems, which appeared with the title of *Ultimos Cantos* in 1850, was practically the poet's farewell to Rio de Janeiro and the service of the muse, for he spent the next eight years engaged under Government patronage in obtaining a personal acquaintance with the scientific institutions of Europe, was appointed on his return to Brazil a member of an expedition for the exploration of the province of Ceara, was forced in 1862 by the state of his health to try the effects of another visit to Europe, and died in September 1864 on board the vessel that was bearing him once again to his native shores. While in Germany he published at Leipzig a complete collection of his lyrical poems, which has since gone through several editions; the four first cantos of an epic poem called *Os Tymbnos* (1857); and a *Diccionario da lingua Tupy* (1858). To the publications of the Rio de Janeiro Geographical and Historical Institute he contributed a number of papers, among which the one on *Brazil and Oceania* has received special notice. A complete edition of the works of Dias has made its appearance at Rio de Janeiro. See Francisco Suter in the *Rivistan Maranhense*, and Wolf, *Brasil Littéraire*.

DIAS, BAROLOMEO, a Portuguese navigator, the discoverer of the Cape of Good Hope, flourished towards the close of the 15th century, the date of his birth being unknown. He seems to have interested himself at an early period in geographical research, and to have been intimate with Martin Behem. In August 1486 he was appointed by King John II. to the command of a small expedition intended to carry on the work of exploration on the coast of Africa. After touching at various points on the western shore of the continent, and taking possession of them for his royal master, he sailed onward into the unknown sea and doubled the Cape without being aware of it. He touched land at the mouth of the Great Fish River. He now found that he had rounded the continent, and in his return voyage he sighted the promontory to which he gave the name *Cabo Tormentoso*, or *Cabo de todos los tormentos* (Cape of all the Storms). This was afterwards changed by the king for the happier title it still bears. Dias arrived in Lisbon in December 1487. He afterwards commanded a ship in the first expedition of Vasco da Gama, who sent him back to Portugal after they had reached the Cape Verd Islands. He held a similar position in the expedition under Cabral which discovered Brazil. On the return voyage the vessel he commanded foundered in a storm on the 29th May 1500.

DIATOMACEÆ For the knowledge we possess of these beautiful organisms, so minute as to be undiscernible by our unaided vision, we are indebted to the assistance of the microscope. It was not till towards the close of the last century that the first known forms of this group were discovered by O. F. Muller. And so slow was the progress of discovery in this field of scientific research that in the course of half a century, when Agardh published his

Systema Algarum in 1824, only 49 species included under 8 genera had been described. Since that time, however, the microscope has been greatly improved; and eminent naturalists in all parts of the civilized world have been induced to engage in the study of these forms. The result is that the number of known genera and species has been greatly increased, the species found in Great Britain and Ireland may be estimated at little less than 1000, and Rabenhorst, in the index to his *Flora Europæa*, enumerates about 4000 forms which have been discovered throughout the continent of Europe. At a time when little was understood of the structure of these organisms they were generally known among botanists by the appellation of Bacillariaceæ; but almost all recent authors are agreed in adopting the later and more appropriate designation of Diatomaceæ.

Various opinions have been entertained as to the position to be assigned to these forms. The earlier observers referred them to the vegetable kingdom. Subsequent authors, including Ehrenberg, regarded them as animals; but in consequence of their analogy to other organisms acknowledged to be vegetable, as regards their general structure, and more especially their modes of reproduction, they are now almost universally included in the vegetable kingdom, and classified with the Monocellular Algæ.

The Diatomaceæ exhibit great variety in form. While some species are circular, as *Coscinodiscus perforatus* (fig 1), others are of an oval outline, as *Sunrella ovalis* (fig. 2)

FIG 1 — *Coscinodiscus perforatus* × 400

FIG 2 — *Sunrella ovalis* × 400

Some are linear, as *Synedra radians* (fig 3); others more

FIG 3. — *Synedra radians* × 200.

or less crescentic, as *Epithemia hyndmanni* (fig 4); others,

FIG 4 — *Epithemia hyndmanni* × 400.

again, are cuneate, as *Podosphecia lynghyii* (fig 5); some few have a sigmoid outline, as *Pleurosigma balticum* (fig. 6), but the prevailing forms are naviculoid, as *Navicula cuspidata* (fig 7). They vary greatly also in their modes of growth,—some being free, others attached to foreign bodies by gelatinous stipes, the stipes being in some species very short, while in others they are of considerable length. In some genera the forms are simple, while in others the frustules are connected together in ribbon-like filaments, or form, as in other cases, zig-zag chains. In some genera the frustules are naked, while in many others they are inclosed in a more or less definite gelatinous investment, or frond,

FIG 5 — *Podosphecia lynghyii* × 400.

as this covering is usually designated. The conditions necessary to their growth are moisture and light. Wherever these circumstances coexist, diatomaceous forms will almost invariably be found. They occur mixed with other organisms on the surface of moist rocks; in streamlets and

FIG 6.—*Pleurosigma balticum*. ×200.

poools, they form a brownish stratum on the surface of the mud, or cover the stems and leaves of water plants or floating twigs with a furry investment. Marine forms are usually attached to various sea-weeds, and many are found

FIG. 7.—*Navicula cuspidata*. ×400.

in the stomachs of molluscs, holothurians, ascidians, and other denizens of the ocean. The fresh-water forms are specifically distinct from those incidental to salt or brackish water,—fresh-water species, however, are sometimes carried some distance into the sea by the force of the current, and in tidal rivers marine forms are carried up by the force of the tide. Some notion may be formed of the extreme minuteness of these forms from the fact that one the length of which is $\frac{50}{100000}$ ths of an inch may be considered as beyond the medium size. Some few, indeed, are much larger, but by far the greater proportion are of very much smaller dimensions.

Structure.—These minute vegetables are distinguished from kindred forms by the fact of having their soft vegetative part covered by a siliceous case. This covering of silica consists of two similar valves nearly parallel to each other, each valve being furnished with a rim projecting from it at a right angle. One of these valves with its rim is slightly smaller than the other, the smaller fitting into the larger pretty much as a pill box fits into its cover. This peculiarity of structure affords ample scope for the growth of the cell-contents usually known as the endochrome. As the endochrome increases in volume the siliceous valves are pushed out, and their corresponding siliceous rims become broader.

As regards the vegetative contents of this cell, in so brief a description the following parts only need to be referred to. There is first what Pfitzer, a distinguished German writer on this subject, designates the plasmasac, consisting of a fine colourless plasma forming a closed sac of the same shape as that of the cell. The refractive power of this plasma differing but slightly from that of water, the presence of this structure is not always obvious, but on the application of hydrochloric acid its outline may be discerned as it slowly separates from the cell wall,—at first preserving the shape of the cell, but ultimately contracting into a small round mass. Within the plasmasac is the structure which the writer just named designates the endochrome-plates. They consist of a thick substance, and are of the same colour throughout, varying from bright yellow to a dark yellowish brown. The number and position of the endochrome plates vary in the different genera—some having two, others only one. Within the folds of these plates is sometimes noticeable a collection of plasma which Ehrenberg describes as resembling the embryo in an egg, and which Pfitzer calls the middle plasmasac. Within this plasmasac oil globules and vacuoles are diffused, and in the centre of it a small vesicle may often be observed.

Motion.—One of the first phenomena which comes under

the notice of the observer is the extraordinary power of motion with which the frustules are endowed. Some species move slowly backwards and forwards in pretty much the same line, but in the case of *Bacillaria paradoxa* the motion is very rapid, the frustules darting through the water in a zig-zag course. To account for this motion various theories have been suggested, none of which appear to be altogether satisfactory. So while the extraordinary motion of the Diatomaceæ excites admiration, it must be acknowledged that the mechanical agency which produces the motion remains unexplained.

Classification.—In this group, as well as in almost all others, various systems of classification have from time to time been adopted, but that which seems to commend itself most strongly, as well by reason of its simplicity as its facility of application, is the system which has been matured by Heiberg, the distinguished Danish writer on the subject, and which he has founded on the symmetrical or unsymmetrical form of the frustule in its several aspects. A diatomaceous frustule may be regarded on what is called the front view, in which the connecting rim or hoop is seen, or on the side view, by which the valve is presented to the eye of the observer. If the outline be symmetrical both on the transverse and longitudinal axis, in both these aspects the frustule is said to be symmetrical; but if the outline be different on one side from that of the other, or if perfect symmetry does not exist as respects the longitudinal or transverse axis, the frustule is said to be unsymmetrical on the aspect or axis in which want of symmetry is found to exist.

Reproduction.—In the Diatomaceæ, as well as in the Desmidiæ, the ordinary mode of increase is by self-division of the cell (see ALGÆ, vol. i p. 508). The cell-contents within the inclosure of the siliceous case separate into two distinct masses. As these two masses of endochrome become more and more developed, the valves of the mother cell are pushed more and more widely apart. A new siliceous valve is secreted by each of the two masses on the side opposite to the original valve. When this process has been completed the hoop of the mother frustule gives way, and two distinct frustules are formed, the siliceous valves in each of these new frustules being one of the valves of the mother cell, and a newly formed valve similar and more or less parallel to it.

During the life of the plant this process of self-division is continued with an almost incredible rapidity. On this subject the observation of the late Professor Smith is worthy of special notice—"I have been unable to ascertain the time occupied in a single act of self-division, but supposing it to be completed in twenty-four hours we should have, as the progeny of a single frustule, the amazing number of 1,000,000,000 in a single month, a circumstance which will in some degree explain the sudden, or at least rapid, appearance of these organisms in localities where they were a short time previously either unrecognized or sparingly diffused" (*British Diatomaceæ*, vol. i. p. 25).

Some authors of reputation have been under the impression that the Diatomaceæ, like other kindred forms, are sometimes reproduced by zoo-pores, and some few facts from time to time have been recorded by various observers which seem to bear out this view of the case. But in this group, as well as in the Desmidiæ already referred to, there obtains another mode of reproduction which is generally known as conjugation. It would be unnecessary here to describe in detail the various observed modes of this process. Suffice it to say that usually two parent frustules unite, invest themselves in a gelatinous sac in which their cell contents are discharged and formed into two bodies termed sporangia, which soon are developed into two frustules in all respects resembling the parents but usually

double their size. In some phases of this process the gelatinous sac bears a considerable resemblance to that lowest form of animal life known by the name of *Amœba*, so much so that an inexperienced observer might suppose that the object before him was an *Amœba* gorged with diatomaceous frustules.

Mode of Preparation.—The Diatomaceæ are usually gathered in small bottles, and special care should be taken to collect them as free as possible from extraneous matter. A small portion having been examined under the microscope, should the gathering be thought worthy of preservation, some of the material is boiled in acid for the purpose of cleaning it. The acids usually employed are hydrochloric, nitric, or sulphuric, according as circumstances require. When the operator considers that by this process all foreign matter has been eliminated, the residuum is put into a precipitating jar of a conical shape, broader at the bottom than at the top, and covered to the brim with filtered or distilled water. When the diatoms have settled in the bottom of the jar, the supernatant fluid is carefully removed by a syringe or some similar instrument, so that the sediment be not disturbed. The jar is again filled with water, and the process repeated till the acid has been completely removed. It is desirable afterwards to boil the sediment for a short time with supercarbonate of soda, the alkali being removed in the same manner as the acid. A small portion may then be placed with a pipette upon a slip of glass, and, when the moisture has been thoroughly evaporated, the film that remains should be covered with dilute Canada balsam, and, a thin glass cover having been gently laid over the balsam, the preparation should be laid aside for a short time to harden, and then is ready for observation.

General Remarks.—Like all other organisms, the Diatomaceæ doubtless have a definite function assigned to them in the grand system of creation, but a special interest attaches to them. Allusion has been made to the fact that the soft cell of these organisms is encased in a siliceous epiderm. When the plant has fulfilled its natural course the siliceous covering sinks to the bottom of the water in which it had lived, and there forms part of the sediment. When in the process of ages, as it has often happened, the accumulated sediment has been hardened into solid rock, the siliceous exuviae of the diatoms remain unaltered, and, if the rock be disintegrated by natural or artificial means, may be removed from what has been called "their stony shroud," and subjected to examination under the microscope. The forms found may from their character help in some degree to illustrate the conditions under which the stratum of rock had been originally deposited.

Vast deposits of Diatomaceæ have been discovered in various parts of the world,—some the deposit of fresh, others of salt water. Of these deposits the most remarkable for extent, as well as for the number and beauty of the species contained in it, is that of Richmond, in Virginia, one of the United States of America. It is said to extend for many miles, and to be in some places at least 40 feet deep. The material has long been used as a polishing powder, and recently has been largely employed in the manufacture of the powerful explosive agent known as dynamite. It is a remarkable fact that existing species of Diatomaceæ have been traced so far down as the lower strata of the Tertiary formation; and, though the generations of a diatom in the space of a few months far exceed in number the generation of man during the period usually assigned to the existence of the race, the fossil genera and species are in all respects to the most minute details identical with the numerous living representatives of their class.

(E. O'M.)

DIAZ DE LA PEÑA, NARCISSE VIRGILE (1809–1876), a French artist, distinguished chiefly as a landscape painter,

was born at Bordeaux in August 1809. His first works were exhibited at the Salon in 1831, and attracted little notice, being poor in colour, the quality for which he afterwards became conspicuous. The same criticism applies to the pictures he exhibited annually until 1840, when his style underwent a decided change. His *Nymphes de Calypso* (1840), *Le Rêve* (1841), *Vue de Bas-Bréau, L'Orientale*, *Le Maléfice*, and *Les Bohémiens se rendant à une Fête* (1844), showed in an increasing degree the richness of colour and the mastery of the more subtle effects of light and shade which ultimately obtained for Diaz a place in the first rank of landscape painters. His powers were seen at their best in his *Baigneuse* and *L'Amour désarmé* (1851), and in the pictures he sent to the Paris Exhibition of 1855, *Les Présents d'Amour*, *La Rivale*, *La fin d'un Beau Jour*, *Nymphe Endormie*, *Les Dernières Larmes*, &c. As the titles of several of these works indicate, Diaz endeavoured to add to the interest of his landscapes by introducing into them the personages of the classical mythology. Late in his career he devoted himself to *genre* subjects with but indifferent success. Diaz received a medal of the third class in 1844, of the second class in 1846, and of the first class in 1848; and in 1851 he was made a chevalier of the Legion of Honour. He died in November 1876.

DIBDIN, CHARLES (1745–1814), a well-known writer of songs and musical composer, was born at Southampton on the 15th March 1745, and was the youngest of a family of eighteen. His parents designing him for the church, he was sent to Winchester; but his love of music early diverted his thoughts from the clerical profession. After receiving some instruction from Kent, the organist of Winchester Cathedral, he went to London at the age of fifteen. In the following year his first work, an operetta entitled *The Shepherd's Artifice*, with words and music by himself, was produced at Covent Garden Theatre. This proved successful, and was followed by other works, his reputation being firmly established by the music to the play of *The Padlock*, which was produced at Drury Lane under Garrick's management in 1768, the composer himself taking the part of Mungo. He continued for some years to be connected with Drury Lane, both as composer and as actor, and produced during this period two of his best known works, *The Waterman* (1774) and *The Quaker* (1775). A quarrel with Garrick led to the termination of his engagement, and in 1782 he became joint manager of the Royal Circus, afterwards known as the Surrey Theatre. In three years he lost this position owing to a quarrel with his partner. In 1788 he sailed for the East Indies on the invitation of a sailor brother (the "Tom Bowling" of his famous song); but, the vessel having put in to Torbay in stress of weather, he changed his mind and returned to London. A series of mono-dramatic entertainments which he gave at his theatre, *Sans Souci*, in Leicester Square, brought his songs, music, and recitations more prominently into notice, and permanently established his fame as a lyric poet. It was at these entertainments that he first introduced many of those sea songs which so powerfully influenced the national spirit. The words breathed the simple loyalty and dauntless courage that are the cardinal virtues of the British sailor, and the music was appropriate and naturally melodious. Their effect in stimulating and ennobling the spirit of the navy during the war with France was so marked as to call for special acknowledgment. On retiring from public life, in 1805, Dibdin was rewarded by Government with a pension of £200 a year, of which he was only for a time deprived under the administration of Lord Grenville. Dibdin died of paralysis in 1814. Besides his *Musical Tour through England* (1788), his *Professional Life*, an autobiography

published in 1803, a *History of the Stage* (1795), and several smaller works, he wrote upwards of 1400 songs and about 30 dramatic pieces. He also wrote one or two novels which are now forgotten. An edition of his songs by G. Hogarth (1843) contains a memoir of his life. The edition prepared by his son Thomas is referred to below.

DIBDIN, THOMAS (1771–1841), English dramatist and song writer, was one of the sons of the subject of last notice, and was born on the 21st of March 1771. He was apprenticed to a London upholsterer, but after four years' service he broke his engagement and joined a company of country players. From 1789 to 1795 he performed in every department of the drama, composing during the same period more than 1000 songs, and making his first attempt as a dramatic writer. He returned to London in 1795, having married two years before; and in the winter of 1798–1799 his *Jew and the Doctor* was produced at Covent Garden. From this time he contributed a very large number of comedies, operas, farces, &c. to the public entertainment. Some of these brought immense popularity to the writer and immense profits to the theatres. It is stated that the pantomime of *Mother Goose* produced more than £20,000 at Covent Garden Theatre, and the *High-mettled Racer* £18,000 at Astley's. Notwithstanding this run of popularity, and the author's connection with theatrical notabilities, his last years were passed in comparative indigence. In 1827 he published two volumes of *Reminiscences*, and at the time of his death he was preparing an edition of his father's sea songs, for which a small sum was allowed him weekly by the lords of the Admiralty. He died in London, September 16, 1841.

DIBDIN, REV. THOMAS FROGNALL (1776–1847), an enthusiastic bibliographer, born at Calcutta in 1776, was the son of Thomas Dibdin, the sailor brother of Charles Dibdin, whom the latter has immortalized in his song "Poor Tom Bowling." His father and mother both died on the voyage home to England in 1780, and he was brought up by a maternal uncle. He was educated at St John's College, Oxford, but left the university without taking his degree. Intended for the bar, he was entered at Lincoln's Inn, and studied for a time in the chambers of Basil Montague. After an unsuccessful attempt to obtain practice as a provincial counsel at Worcester, he resolved to abandon law for the church, and he was ordained a clergyman at the close of 1804. His ecclesiastical preferment was slow. For a number of years he had to content himself with the appointment of preacher at various chapels in the West End of London, and it was not until 1823 that he received the living of Exning in Sussex. Soon afterwards he was appointed by Lord Liverpool to the rectory of St Mary's, Bryanstone Square, which he held until his death on the 18th November 1847. The first of the numerous bibliographical works on which Dibdin's fame entirely rests was his *Introduction to the Knowledge of the Rare and Valuable Editions of the Latin and Greek Classics* (1803), which, though superficial, incomplete, and untrustworthy in many of its details, supplied a blank in English literature. A fourth and greatly enlarged edition appeared in 1827. The first edition rendered a valuable service to its author in bringing him under the notice of Earl Spencer, to whom he owed not only his first living but much important aid in his bibliographical pursuits. The rich library at Althorp was thrown open to him; he spent much of his time in it, and in 1814 published his *Bibliotheca Spenceriana*, giving an account of the many rare works it contained. As the library was not open to the general public, the information given in the *Bibliotheca* was found very useful, but the work was marred by the inaccuracy in matters of detail which more or less

characterized all its author's productions. This fault was naturally least obtrusive in a series of playful, discursive works in the form of dialogues on his favourite subject, in which great exactness was not necessary. The first of these, *Bibliomania* (1809), was republished with large additions in 1811, and was very popular, passing through numerous editions. To the same class belonged the *Bibliographical Decameron*, a larger work, which appeared in 1817, and has a higher value than its predecessor, though it did not attain the same circulation. In 1810 he commenced the publication of a new and much extended edition of Ames's *Typographical Antiquities*. The first volume was so great a success that Dibdin realized £600 by it. This, however, was not maintained, and the fourth volume, which did not appear until 1819, fell almost still-born from the press. The work was scarcely half-finished when its publication was thus checked. The chief cause of its failure was that Dibdin had not critical sagacity enough to make a thorough change in the arrangement his predecessor had followed, and to enable him to distinguish what was valuable from what was worthless in the vast stores of information he had himself collected. In 1818 Dibdin was commissioned by his patron, Earl Spencer, to purchase books for him on the Continent, and he afterwards published an account of his journey in his *Bibliographical, Antiquarian, and Picturesque Tour in France and Germany* (3 vols. 1821), which was got up in a most sumptuous style, the engravings alone, it is said, costing £5000. In 1824 he published an ambitious venture in his *Library Companion, or the Young Man's Guide and Old Man's Comfort in the Choice of a Library*, which was intended to point out the best works in all departments of literature. His culture was not broad enough to render him competent for the task, and the *Library Companion*, being severely criticized in the *Quarterly* and *Westminster Reviews*, seriously injured his reputation. He had been for some time involved in pecuniary difficulties, from which he tried to free himself with only partial success by extending the range of his literary activity. He wrote for periodicals, published many of his sermons, and for some years gave himself chiefly to religious literature. He returned to bibliography in his *Bibliophobia, or Remarks on the Present Depression in the State of Literature and the Book Trade* (1831), and the same subject furnishes the main interest of his *Reminiscences of a Literary Life* (1836), and his *Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and Scotland* (1838). Dibdin was the originator and vice-president. Lord Spencer being the president of the Roxburghe Club, founded in 1812,—the first of the numerous book clubs which have done such service to literature in the present century.

DICÆARCHUS, a celebrated Peripatetic philosopher, historian, and geographer, was a native of Messana, in Sicily. He was the contemporary of Theophrastus and Aristotle, and flourished towards the close of the 4th century B.C. The exact dates of his birth and death are unknown; the time of the latter event is approximately fixed by good authorities as the year 285 B.C. Nothing is known with certainty concerning the life of Dicæarchus except that he was a disciple of Aristotle and a friend of Theophrastus, to whom he dedicated the majority of his works. Of his writings, which comprised treatises on a great variety of subjects, none have descended to our day. Nothing but their titles and a few fragments survive. The most important of them was his *Life in Greece*, in which the moral, political, and social condition of the people was very fully discussed. Among the philosophical works of Dicæarchus may be mentioned the *Lesbiaci*, in three books, in which the author endeavours to prove that the soul is mortal. This work is written in the form of a dialogue,

and derived its name from the fact that the scene of the dialogue was laid at Lesbos. To it the author afterwards appended a supplement, likewise in three books, which he called *Corinthiaci*. The only complete edition of the fragments of Dicaearchus is that published at Darmstadt in 1841 by Max Fuhr. An excellent dissertation on them will be found in Osann, *Beitrag zur Griech. und Rom. Literatur*.

DICK, THOMAS (1775–1857), a popular writer on astronomy and other scientific subjects, was born in 1775. He was educated for the ministry in connection with the Secession (now United Presbyterian) Church of Scotland, and was ordained at Stirling in 1803. About two years afterwards his connection with the church was severed, and he became a teacher, first at Methven, a village in Perthshire, and afterwards at Perth. In 1824 he published in two volumes the *Christian Philosopher*, a work whose "aim was," in his own words, "to illustrate the harmony which subsists between the system of nature and the system of revelation, and to show that the manifestations of God in the material universe ought to be blended with our view of the facts and doctrines recorded in the volume of inspiration." The success of this work enabled him to resign his labours as teacher, and in 1827 he removed to Broughty Ferry, a suburb of Dundee, where he devoted his whole time to literary and scientific pursuits. Besides the *Christian Philosopher*, he is author of the *Philosophy of a Future State* (1828), the *Improvement of Society by the Diffusion of Knowledge* (1833), *Celestial Scenery* (1837), *The Sidercal Heavens* (1840), and several smaller treatises. These works were all intended to supplement and extend the aims of the *Christian Philosopher*, and may be regarded as endeavours by means of scientific discoveries to illustrate particular aspects of religious truth, and to suggest solutions of difficult religious problems. They are written in a popular and fascinating style, and manifest great aptitude for simplifying scientific subjects, and rendering them interesting to non-scientific readers. Some years before his death, which took place 27th July 1857, a pension was conferred on him by Government.

DICKENS, CHARLES (1812–1870), the great English novelist, was what would generally be described as a self-educated man, and yet, if by a man's education we understand preparation for the work he has to do in life, he was indebted to circumstances for an education on which it would have been difficult to improve. His father was a clerk in the Navy Pay Office, stationed at Portsmouth when Charles was born, but soon afterwards at Chatham, and soon after that in London,—a conscientious man, industrious and punctual in his occupation, but too easy tempered and unpractical to expend his income so as to keep pace with the wants of a rapidly increasing family. The boy's mother seems to have been a person of more energy, as well as of considerable accomplishments; she taught him the rudiments of Latin, and tried to establish a boarding school in Gower Street. The one parent was the original of Micawber, the other the original of Mrs Nickleby. With all their united efforts they could not keep out of distress; the boarding school scheme came too late; and when Dickens was nine years old the family was living in abject poverty in Bayham Street, Camden Town, then one of the poorest London suburbs, and their difficulties were increasing upon them. Charles was sent out to earn six shillings a week in a blacking warehouse, tying blue covers on pots of paste-blackening. For two years the child led a very hard, uncared-for life at this uncongenial work. He bitterly felt that it was uncongenial, for he was a very precocious boy, had read many books, and had formed an ambition to be "a learned and distinguished man." It must have been very galling to him, with his

prematurely developed sensibilities and aspirations, to be thrown among such companions as Bob Fagin and Poll Green. And perhaps he was right in afterlife to wonder at the thoughtlessness of his parents in subjecting him to such a humiliation. His sufferings were so acute, and made such an impression on him, that years afterwards he could not think of them without crying; and there were certain quarters of the town through which he used to pass to his daily work, and where he used to loiter with less than enough to eat, that he habitually shunned for their painful memories. "It is wonderful to me," he wrote when in the height of his fame, "how I could have been so easily cast away at such an age. It is wonderful to me that, even after my descent into the poor little drudge I had been since we came to London, no one had compassion enough on me—a child of singular abilities, quick, eager, delicate, and soon hurt, bodily or mentally—to suggest that something might have been spared, as certainly it might have been, to place me at any common school. Our friends, I take it, were tired out. No one made any sign. My father and mother were quite satisfied. They could hardly have been more so if I had been twenty years of age, distinguished at a grammar school, and going to Cambridge."

And indeed, if his parents could have foreseen the future, they would have had cause to be much more satisfied. For when the fragile little boy was sent into his cousin's blacking warehouse, he entered a better school, as it happened, than his father could have chosen for him. It was an infinitely more painful school than Harrow or Eton, but for one whose destined work was to describe the poorer houses and streets of London, and the many varieties of life, odd and sad, laughter-moving and pitiful, that swarmed in them, it was a more instructive school, it was the true road to knowledge. The chances were that a delicate boy like him succumbed to his wretchedness, and that a clever boy like him became a rogue and vagabond; but he survived these dangers and became a great novelist. Instead of sinking into the depths of the thronging atoms, he rose above them, or kept apart from them, observed them, and became their describer.

It is impossible to say how this watchful habit began, and when it connected itself with his love of literary distinction. We have Dickens's own testimony that he was a singularly observant child, and that at a very early period he had an ambition to become "a learned and distinguished man," but it would be going too far to suppose that from his childhood he held himself apart and kept a keen eye on the doings of others with a view to making capital out of his observations. At first in all likelihood the distinction which he coveted was a kind of distinction that seemed to him possible only through the medium of grammar-schools and universities. To the last no doubt he regretted this want of academical study, and believed that it had placed him at a disadvantage. Still accident is so very much better a schoolmaster than design, that from the first it gave him also the literary training needful to make him a painter of manners. His father, the navy pay clerk, had a small collection of books, with which the "very small and not over-particularly taken care of boy" had made himself familiar while he was living at Chatham, before his experiences in Camden Town and the blacking warehouse. Among these books were *Roderick Random*, *Percegrine Pickle*, *Humphrey Clinker*, *Tom Jones*, *the Vicar of Wakefield*, *Don Quixote*, *Gil Blas*, *Robinson Crusoe*, *the Arabian Nights*, Mrs Inchbald's *Farces*, and the *Tales of the Genii*. This literature did not glide over the boy's mind like water over marble; it found congenial soil, and fell into it as seed. He lived the life of his favourite characters. "I have been Tom Jones," he says, putting his own case into the mouth of David Copperfield "a child's Tom Jones, a

harmless creature), for a week together. I have sustained my own idea of Roderick Random for a month at a stretch, I verily believe. I had a greedy relish for a few volumes of voyages and travels—I forget what now—that were on these shelves; and for days and days I can remember to have gone about my region of our house, armed with the centre-piece out of an old set of boot-trees, the perfect realization of Captain Somebody of the Royal British navy, in danger of being beset by savages, and resolved to sell his life at a great price." And then follows something still more suggestive, as showing his tendency to connect these ideal creations with the world of sense around him. "Every barn in the neighbourhood, every stone in the church, and every foot of the churchyard had some association of its own in my mind, connected with these books, and stood for some locality made famous in them. I have seen Tom Piper go climbing up the church steeple; I have watched Strap, with the knapsack on his back, stopping to rest himself upon the wicket gate; and I know that Commodore Truncheon held that club with Mr Pickle in the parlour of our little village alehouse." Even thus early, too, he tried to imitate what he read, wrote a tragedy founded on one of the *Tales of the Genii*, and acquired great fame in his own circle as a teller of stories.

A boy with this preliminary training was excellently prepared for a course of strange and painful experiences. The bitter contrast between the ideal world in which he had lived, and the miserable poverty in which he spent the first three years of his life in London, making himself useful at home, running errands, carrying things to the pawn-brokers, visiting his father in the Marshalsea, into which the poor man and his family soon drifted, tying up pots of blacking at the warehouse, prowling about cook-shops, à-la-mode beef-shops, and coffee-shops, a shabbily clad and insufficiently fed little boy, seeking to invest his livelihood of a shilling a day to the best advantage, helped to fix these experiences and the many odd scenes and characters with which they brought him in contact more indelibly on his memory. According to his own account, intensely as he felt the misery and shame of this kind of life, he was not without a perception of its humorous side. He used to say that, incredible as it might appear, he looked upon things then very much as he did afterwards. He even began to make attempts to sketch what he saw. Colman's *Broad Grins* was lent him by some kind people—another wise provision on the part of the great schoolmaster Accident; and with this before him as a stimulus, he actually sketched the barber who came to shave his bachelor uncle, the old charwoman who helped his mother, and laid the foundation of subsequent sketches,—Mrs Pipchin, the little Marchioness, Bob Sawyer's lodgings, and many other characters and scenes to which we have not the same direct traces. He was pursuing his education, in fact, as thoroughly as if he had been a pupil in a painter's studio. He was serving his apprenticeship. He could not have been better employed if he had been the holder of an endowment for research.

Dickens himself by no means looked upon it in that light. It was with difficulty, twenty-five years afterwards, that he could bring himself to speak of this period of his life. In his eyes it was a miserable servitude, from which he was happily relieved by a quarrel between his father and one of the partners in the warehouse when he was rather more than twelve years old, and sent to a school in Mornington Place, where he consorted with more respectable boys, and had some chance of book learning. If his father's fortunes had been equal to it, he might now have passed through a regular course of grammar-school and university training, and thereby perhaps been incapacitated for the work to which he was called. But

fortunately he was soon again thrown chiefly on his own resources. At the age of fifteen he was engaged as an office-boy by an attorney in Gray's Inn at a salary of 13s. 6d., and afterwards 15s. a week. Here again he had a good field for observation, and did not fail to use it, for his employer afterwards recognized in *Pickwick* and *Nickleby* several incidents that took place in his office, and professed also to identify some of the characters. With Mr Blackmore he remained for eighteen months. During that time his father became a newspaper parliamentary reporter, and the office-boy, who had lost none of his thirst for distinction, and spent all his spare time reading hard in the British Museum, resolved to qualify himself for a similar occupation. He mastered the difficulties of short-hand, and in November 1828 obtained employment as a reporter in Doctors' Commons. He spent two years reporting law cases, practising in Doctors' Commons and the other law courts. It would be difficult to conceive a more perfect way of completing the education of the future novelist, giving him an insight into the strange by-paths of that higher stratum of society of which he had before had little experience. At the age of nineteen he entered the parliamentary gallery to enlarge his knowledge still further. He was a reporter of political speeches in and out of Parliament for five years from 1831 to 1836. First he reported for the *True Sun*, then for the *Mirror of Parliament*, finally for the *Morning Chronicle*. In his excursions into the country, and back with his "copy," he saw the last of the old coaching days and of the old inns that were a part of them; but it will be long, as Mr Forster remarks, "before the readers of his living page see the last of the life of either."

His first published piece of original writing appeared in the *Old Monthly Magazine* for January 1834. The title was "A Dinner at Poplar" ("Mr Minns"), one of the pieces afterwards published as *Sketches by Boz*, the *nom de plume* which he adopted from the nickname of one of his brothers. He wrote nine of these sketches for the *Monthly Magazine*, and then he was engaged to write some for an evening offshoot to the *Morning Chronicle*. The first series of *Sketches by Boz* was collected and published in two volumes in the February of 1836, with illustrations by George Cruikshank. The first edition was exhausted in a few months; a second was called for in August. The *Sketches* had at once attracted attention. No wonder, for in them we find already in full swing the unflagging delight in pursuing the humorous side of a character, and the inexhaustible fertility in inventing ludicrous incidents, which had only to be displayed on a large scale to place him at once on a pinnacle of fame. There are many of them, such as the Parish, the Boarding House, Mr Minns and his Cousin, and the misplaced attachment of Mr John Dounce, which show Dickens's humour at its very richest. He had formed, too, by this time his characteristic likes and dislikes, and plays them off upon his butts and favourites with the utmost frankness. The delight in homely sociability and cheerfulness, in the innocent efforts of simple people to make merry, the kindly satire of their little vanities and ambitions, the hearty ridicule of dry fogies who shut themselves up in selfish cares and reserves, and of sour mischief-makers who take pleasure in conspiring against the enjoyment of their neighbours,—these tendencies, which remained with Dickens to the last, are strongly marked in the *Sketches*, though lighter-hearted in their expression than in his later works. The mark and indispensable condition of all great work is there, that which Mr Carlyle calls veracity—the description of what the writer has himself seen, heard, and felt, the fearless utterance of his own sentiments in his own way.

The first number of *The Posthumous Papers of the*

Pickwick Club was issued in April 1836. The story of its origin was first authentically told in the preface to the edition of 1847. Some of the details were afterwards slightly modified. The first thought of the work did not originate with Dickens, although the whole character of it was determined by him. The publishers, Messrs Chapman & Hall, and Mr Seymour the artist, had agreed to issue a monthly serial to be illustrated by Mr Seymour, and they went to Dickens, whose *Sketches* had attracted their attention, to propose that he should write the letterpress of this "monthly something." Their idea was that the author should describe the adventures of a "Nimrod Club," the members of which should go out shooting, fishing, and so forth, and getting themselves into difficulties through their want of dexterity. Dickens undertook the monthly something, but obtained the required diverting incidents by a different machinery, namely, the *Pickwick Club*. The first four numbers went off slowly; the demand first became "brisk" after the fifth number, in which Sam Weller made his appearance. But by the discerning few the value of the work was recognized; and one of them, Mr Bentley the publisher, only a few weeks before fame came to the author with its capricious and overwhelming suddenness, engaged him to undertake the editing of a monthly magazine to be started the following January, and to write a serial story for it, and further made an agreement with him for the writing of two other tales at a specified early date. Of the vexation arising out of this agreement, when the huge success of the *Pickwick Papers* showed its terms to be inadequate, and Dickens was disposed to resent it as a selling of himself into slavery, and of the manner in which the bargain was re-adjusted, an account is given by Mr Forster from the author's point of view. Nine monthly numbers of the *Pickwick Papers* were published in 1836; eleven more in 1837; by November of the latter year the sale had reached 40,000 copies, *Pickwick* had become a popular hero and godfather to innumerable articles of merchandise, and Sam Weller's sayings were catchwords in the street and the household wherever the English language was spoken.

In the first excitement of success, the young author's appetite for work was unbounded. In 1837 he wrote his monthly instalments of the *Pickwick Papers* and *Oliver Twist* side by side, not even by a week in advance of the printer with either. They kept him fully occupied, and held him in abeyance for that year a taste which from his youth to the end of his career was strong in him, and had no inconsiderable influence upon his style as a painter of manners. In his childhood at Chatham he got his first experience of fame as the author of a tragedy; at the school in Mornington Place he and his companions mounted small theatres and acted small plays; when in the attorney's office in Lincoln's Inn Fields he frequented minor theatres, the nature of which he has caricatured in the *Sketches*, and not unfrequently engaged in parts; one of his first published sketches, "Mrs Joseph Porter Over the Way," is a description of private theatricals in a stage-struck family. In 1836, before his serial engagements multiplied, he wrote a farce called the *Strange Gentleman*, and a short comedy with songs called the *Village Coquettes*. It is strange that with this passion for the stage, which he always retained, he should not have written more plays. He probably felt that in this kind of composition he had but the use of his left hand, and did not care to risk his reputation where he had no field for those powers of description and narrative over which he had proved his mastery. But though he did not write plays, and finally sought no outlet for his theatrical longings except in amateur acting and in reading from his own novels, the habit of realizing incidents as they would appear on the stage is unmistakably apparent in his work. He constantly seems to be working up scenes to the pitch

of stage effect, elaborating the actions of his characters as if he were inventing "business" for a player, suggesting, in fact, an exuberance of business far beyond the capabilities of any human performer.

We doubt whether the fact that Dickens did not write plays is explained by saying that his genius was descriptive and narrative, but not dramatic. There is plenty of the raw material of dramatic action in his dialogues. He probably could have written a good acting play if he had tried. His characters are essentially theatrical, though their story is told according to the laws of the novel, and not according to the laws of the drama. The explanation of his not having tried to write plays we take to be simply that he discovered full employment for his powers in another direction before he had applied himself to the art of constructing plays. Dickens was eminently a practical man, and, when publishers were fighting for his novels, he directed his whole energy to meeting the demand without seeking to experiment on other modes of composition. As some compensation to Mr Bentley for releasing him from the strict terms of the agreement we have mentioned, he edited a life of Grimaldi, which was published in 1838; but after that he put his whole strength into the art of writing sketches and serial tales. As soon as *Pickwick* was off his hands, and before *Oliver Twist* was yet completed, he made an agreement with Chapman & Hall "to write a new work, the title whereof should be determined by him, of a similar character and of the same extent as the *Posthumous Papers of the Pickwick Club*," and between April 1838 and October 1839 he produced the *Life and Adventures of Nicholas Nickleby*.

Before the end of the serial publication of *Nickleby*, he had conceived a new project, partly with a view to relief from the strain of writing a continuous story in instalments with the printer at his heels, and partly with a view to getting more profit for himself out of his labours. This was a weekly publication, to be edited by himself, and to contain sketches, essays, tales, adventures, and letters from imaginary correspondents. He was to receive a certain sum every week for what was written, and was besides to share half the profits with the publishers. When the scheme was agreed to by the publishers, he proceeded to release himself from other engagements by resigning the editorship of *Bentley's Miscellany*, and getting clear of his obligation to write *Barnaby Rudge* for Mr Bentley in consideration of his buying the copyright and stock of *Oliver Twist* for £2250. He thus started clear with *Master Humphrey's Clock*, the title upon which he fixed for his new publication. The first number of *Master Humphrey* was issued on April 4, 1840. The sale of the first number was 70,000 copies, but the orders fell off when it was found that there was to be no continuous story. A story in weekly instalments it was thereupon necessary for him to write. A tale which he had begun in his magazine, and put into the mouth of Old Humphrey, was seen to be capable of expansion, and he expanded it into the *Old Curiosity Shop*, finding himself thus driven to his old employment of keeping ahead of the printers with a serial story, the only difference being that the instalments were weekly, and that he had the stimulus of larger profits from his success.

It is necessary in any account of Dickens, if we care to understand his method as a novelist, to give prominence to the conditions under which he worked. All that has been said about the want of plot in his novels finds its true explanation in those conditions. We need not search for deeper causes. His stories being published in instalments, it was indispensable to success that each separate part should have an independent interest; and as each instalment was published before the next was written, it was necessary that he should have a plot leaving him with the

utmost possible freedom of action. Of course, when we say that this explains his method, we do not mean that it accounts for his success, we do not mean to detract from the marvellous genius that enabled him to write with success under such conditions. We are only concerned to shew how the kind of plot that he adopted, and the numerous branches, offshoots, and meanderings which he permitted himself were imposed upon him by circumstances of publication and composition,—were, in fact, necessary to success under these circumstances. A great deal too much has been made of the want of plot in Dickens's novels, as if it were a weakness, as if he had been incapable of constructing a plot,—the truth being that his method was deliberately adopted as that best suited to the position in which he found himself. It is evident that he was very much exercised over this question of plot, as indeed he was on all points touching his art. The *Pickwick Papers* may be put on one side in studying his method, he tumbled as it were into writing them; "no ingenuity of plot," as he himself explained, "was attempted;" they were simply "designed for the introduction of diverting characters and incidents." In his subsequent novels, if the *Pickwick Papers* can be called a novel, he could lay his plans beforehand, and consider how far it was possible to reconcile the introduction of interesting characters and incidents with greater regularity of structure, and he never seems to have solved the problem to his own satisfaction. In *Oliver Twist* he adopted the method of Defoe, and wrote what may be called a biographical novel, the hero of which is involved in a series of complications, arising one after another without being foreseen and calculated for from the beginning. In this way he avoided committing himself too far in advance to engagements which might afterwards prove embarrassing; the coils are laid for Oliver and cleared away more than once in the course of the story. In *Nicholas Nickleby* he reserved similar freedom of action by making Ralph conspire to ruin his brother's children without committing himself at the outset to any particular scheme as the villain's one resource; he thus also makes provision for a series of plots, one after another, and secures a certain unity for the whole by making them all proceed from one malevolent agency, whose motive was formed before the story began. In *Nicholas Nickleby*, however, he departs from certain restraints under which he had laid himself in the construction of *Oliver Twist*; he asserts greater freedom from the bit and bridle of plot in his introduction of diverting incidents which have no proper connection with the main story. Miss La Creevy and the Kenwidges are brought in on the slightest of pretexts, slighter even than that which serves for the introduction of the Mantalins and the Crummles family. But no one can quarrel with a breadth of canvas which the author is able to fill with such figures; the critic can only say that he would have made a mistake if he had limited himself from the scope thereby given for his powers. As in *Nickleby* the moving principle of the story is the malevolent humour of Ralph, so in the *Old Curiosity Shop* the moving principle is the malevolent humour of Daniel Quilp. It is characteristic of Dickens that the uncalculating impulses should have so much influence in the direction of his stories. Fagin has some amount of selfish object in his designs against *Oliver Twist*; but Ralph and Quilp have nothing to gain by their conspiracies except the gratification of pure malice. The counter-agencies to these simple incarnations of the devil are equally disinterested. Oliver's good angel Nancy, Kate Nickleby's Newman Noggs, Little Nell's Kit, and Kit's Dick Swiveller are swayed by impulses of pure generosity. Observe, too, the analogous positions of Mr Brownlow the protector of Oliver, the Cheeryble brothers the protectors of Nicholas, and Mr Garland the

protector of Kit. It is a game between the elementary passions, in which the good triumphs.

Master Humphrey's Clock was allowed to run out in November 1841, with the conclusion of the tale of *Barnaby Rudge*, which followed the *Old Curiosity Shop*. The construction of *Barnaby Rudge* is less simple than that of any of its predecessors; Dickens here attempted a more closely knit form of plot. There are no incidental diversions in this novel, all the characters have some finger in the main story, and every scene tends towards the development of some relation which afterwards has a potent influence on the course of the main events. It is true the Lord George Gordon riots fill so much space as to eclipse for a time the private interests of the novel; but the lives of all the personages whose fortunes we are following are interwoven with the public history with the most elaborate care and consummate skill, and when our fears for the commonwealth in the general storm are allayed, the keenest interest is left for the fates of the individuals that have been involved in the commotion.

Barnaby Rudge cost the author much labour, and after finishing it, and with it *Master Humphrey's Clock*, he felt the need of some change of strain. He had begun to chafe under the weekly form of publication, and fret as to what he might have done with *Barnaby* if he could only have produced it in monthly instalments. This determined him to make an agreement with his publishers for the issue of his next story in the old monthly form. When he projected the *Clock*, one of his schemes was that he should visit Ireland or America, and write from there a series of descriptive papers for it. The *Clock* was discontinued, but the desire to seek fresh fields remained. He accordingly set out for America in January 1842, returning in June, after a reception which might well have turned his head, to write the *American Notes*. He had been run after and stared at by crowds, and cheered with greater enthusiasm than if he had been a crowned potentate, and the people of the United States complained that in these *Notes*, as well as in his fierce endeavours to enlighten them on the subject of copyright, he had made but a poor return for their welcome. He was superfluously aggressive, there is no doubt; but they freely forgave him when he returned some years afterwards.

From whatever cause, the sale of the first number of *Martin Chuzzlewit* (January 1843), in which he returned to the broad and free method of *Nickleby*, only seeking a new motive for his plot in the design of a severe but benevolent old uncle for his nephew's reformation, and the schemes of a pious hypocrite, fell considerably below what he had been led to expect by the sale of his former monthlies. Only 20,000 were sold; his publishers, with whom he had made a very advantageous bargain, irritated him by grumbling; and though the novel obtained still higher praise than any of its predecessors, he was disappointed and discontented, and began to revolve other plans for making a living by his pen. He conceived the idea of writing a Christmas tale, the *Christmas Carol*; but he made much less profit by the enterprise than he made by similar tales afterwards, when he charged less for them and appealed to a wider audience. Although he sacrificed nothing of his individuality in the substance of the tale, and it was no failure in point of reputation, the pecuniary side of the work was for the moment uppermost in his mind, for, large as his income had been, he had exceeded it, and the most popular author of his time was suffering horrors, as he himself said, of "intolerable anxiety and disappointment." This disappointment determined him to live abroad for a time, partly to reduce his expenses, and partly to store his mind with fresh material. He settled at Genoa, and there finished *Chuzzlewit*, and wrote the *Chimes*, his Christmas

tale for 1844, making a brief visit to England to read it to a party of friends and arrange for its publication. He visited the principal towns of Italy in the first months of 1845, returning to England by way of Switzerland in June.

His first work on returning to London was to project a new weekly, to be called the *Cricket*, "price three halfpence, if possible—partly original, partly select, notices of books, notices of theatres, notices of all good things, notices of all bad ones; carol philosophy, cheerful views, sharp anatomization of humbug, jolly good temper, papers always in season, pat to the time of year; and a vein of glowing, hearty, generous, mirthful, beaming reference in everything to home and friends." The scheme for the time fell through. About the same time he "opened communications with a leading member of the Government to ascertain what chances there might be for his appointment, upon one qualification, to the paid magistracy of London; but the reply did not give him encouragement to entertain the notion farther." Soon after he was asked to undertake the editorship of a new daily paper, the *Daily News*, and consented. But a fortnight's experience (from January 21 to February 9, 1846) satisfied him that he was out of his element. He then resolved to go abroad again, and write another novel in shilling monthly numbers. The fruit of this resolution was *Dombey and Son*, the first number of which was issued in October 1846, and the last in April 1848. On resigning the editorship of the *Daily News*, he did not wholly part connection with it; he continued in it from January to March 1846 a series of descriptive letters, which he afterwards published under the title of *Pictures from Italy*. The sale of *Dombey*, which reached 32,000, reassured him in the pursuit of his special calling. He followed it up in 1849 and 1850 with *David Copperfield*.

There is not much room for variety of incident in the life of a novelist securely established in popular favour, working hard, and happy in the exercise of his art. When we have mentioned that *Bleak House* appeared in monthly numbers, from March 1852 to September 1853, *Little Dorrit* from December 1855 to June 1857, *Our Mutual Friend* from May 1864 to November 1865, we have given the chief incidents in the later half of the literary life of Dickens. He was much too restless a man, however, to settle down into a steady routine of work. He was not content to appear before the public only in monthly numbers. He stuck steadily enough to work in which he had proved his mastery, but yet he had always a craving for new experiences, and was always planning new enterprises. While *David Copperfield* was still upon his hands he returned to his old notion of a weekly periodical. At first he thought of calling it *The Shadow*, making it contain, as it were, the observations of "a kind of semi-omniscient, omnipresent, intangible creature," "which should go into any place, by sunlight, moonlight, starlight, firelight, candlelight, and be in all houses, and all nooks and corners, and be supposed to be cognizant of everything, and go everywhere, without the least difficulty, which might be in the theatre, the palace, the House of Commons, the prisons, the unions, the churches, on the railroad, on the sea, abroad, and at home." But on consideration he abandoned this idea, and chose the title *Household Words*. The first number appeared in March 30, 1850. In *Household Words*, besides contributing short stories to the annual Christmas number, Dickens wrote *Hard Times* between April 1 and August 12, 1854. In 1859, in consequence of a quarrel between the editor and the publishers, *Household Words* was discontinued, and *All the Year Round*, practically the same periodical under a new title, took its place. In *All the Year Round*, besides Christmas contributions, Dickens wrote *A Tale of Two Cities* between April 30 and November 26, 1859; the *Uncommercial*

Traveller, between January 28 and October 13, 1860; and *Great Expectations* between December 1, 1860, and August 3, 1861. It is often made a question whether there was any falling off of power in the later works of Dickens. *David Copperfield* would generally be named as the novel in which his power was at its zenith. The question is not one that can be answered by an unqualified yes or no. There is certainly no falling off in descriptive power. The idiom of his dialogue is finer; the wit is perhaps keener and more swift. His characters are more sharply defined; the force with which they are drawn is more delicate. In no point of the novelist's art, whether in the general construction or in the execution of details, is there any sign of failing power; on the contrary the power seems to have become firmer and more sure from practice. Does the fault then lie with the reader? Is it that we have grown tired of his manner? This is probably part of the reason, but yet it is not to be denied that we miss something in the later works. We laugh less over the pages. There are longer "intervallums" of seriousness. Humorous characters are still there in abundance; Joe Gargery, Old Boffin, Silas Wegg, Rumty Wilfer, Septimus Crisparkle, Durdles, Mr Sapsea, are as irresistible as any of their predecessors. But on the whole there is less exuberance of animal spirits. The fun is not so unflagging. It is even less hearty, for there is mixed with our laughter something of contempt or pity for the object of it. Not that it is all laughter and undesigning diversion in any of the earlier works. Dickens belonged to a serious and moralizing generation, he came in with the Reform Bill, and partook largely of the moral spirit of its framers. Even in the joyous *Pickwick Papers* there is a serious blow at prison abuses. *Oliver Twist* is almost as didactic as one of Harriet Martineau's tales. Before writing *Nicholas Nickleby* he went down to Yorkshire like a Government commissioner to inquire into the abuses of the Yorkshire schools. Through all the fresh and boisterous fun of his earlier works, there was an almost declared doctrine that it is our duty to laugh, a sort of protest in favour of laughter, and a denunciation of the dismal as a crime. The same genial doctrine runs also through his later works, but it is urged with a trace of bitterness, and with a greater sensitiveness to the evil principles that oppose it. Dickens was not written out, but he was growing old, and the animal spirits which fed the flame of his marvellous humour began to show symptoms of exhaustion. The quality of his humour was unimpaired, but the quantity had suffered diminution.

Dickens established his first weekly periodical from a desire to draw closer the relations between himself and his readers. He drew those relations still closer in 1858, by beginning a series of public readings of his own works. He had long hungered for this way of giving body and substance to his feeling of success. He had always been eager for the immediate and palpable triumphs of the stage. The idea of taking a hall or theatre and reading from his own books was first mentioned by him in 1844, after he had read the *Chimes* to a small company in Mr Forster's rooms, and he often returned to it, but was obliged to hold it in abeyance for fourteen years, his friends urging that it would be beneath his dignity. In 1858 his resolution was taken in spite of all discouragements, partly, he said, to escape from uneasiness at home, though it may well be believed that his own temper—restless, irritable, and exacting in the midst of his work—was largely to blame for the discomfort from which he suffered. He gave four series of readings, in 1858–59, 1861–63, 1866–67, and 1868–70, appearing in nearly every town of any size in the United Kingdom; and in 1867–68 renewing in this way his acquaintance with the Americans. The success of

these readings was enormous from every point of view. Mr Forster mentions that he remitted from America £10,000 odd as the result of 34 readings.

That Dickens should so long have abstained from appearing as a public reader of his own works, and standing face to face with his audience to enjoy the delight of their effect, notwithstanding his strong desire to do so, is a significant fact. It gives a sort of measure of two things,—the force of his craving for sympathy and applause, and the extent of his patience under conventional prejudices. It was from deference to these prejudices that he abstained; and it required an almost fierce effort on his part to dismiss those prejudices as “humbug,” and “the proprieties of old women.” His attitude towards society, in the narrow sense of the word, was always peculiar. To understand it, we must bear in mind the circumstances of his youth. He seems never to have quite lost a lurking fear that those circumstances exposed him to contempt. He was much too proud and great-hearted a man to give in to such a fear; but it clung to him, and was always demanding a certain struggle to keep it down. Slight as the struggle was, the traces of it are perceptible in his work. We have an evidence of it in the common saying that he never succeeded in painting “a gentleman.” That is not to be got over by calling for a definition of the word; it is a popular expression of a fact, the fact that nearly all the personages in his novels occupying a position in life to which that word would have been applied in his own time are painted in unfavourable colours. Perhaps the course of his stories did not call upon him to paint more favourable specimens of that class, still the fact remains that in Dickens’s attitude towards society there was something of the defensive, even of the aggressive. He faced towards society with a certain air of defiance, with the consciousness of a vast popular multitude behind him, to which he could appeal if they refused him what was his due. He never claimed more than his due, and it was never refused to him. It is perhaps for this reason that the traces of his spirit of revolt against society are so slight as to be more matter of inference than of observation. It is more correct to say that he never tried to paint “a gentleman,” than that he did not succeed. The question can hardly be raised without giving it undue importance, an importance which Dickens himself would have been the first to make light of; for, though he had his full share of the little vanities inseparable from humanity, he was a great man in temper as well as in genius, and littlenesses were of the accidents and not of the essence of his nature.

Dickens’s want of perfect sympathy with the cultured society of his time incapacitated him for that kind of novel which answers to comedy in dramatic composition, although it left him free for work of a greater and more enduring kind. What may be called the comedy novel, the novel of Thackeray in Dickens’s generation, is much less sure of enduring fame, because the sentiments on which it rests, being the product of a particular knot of circumstances, are more fugitive, and pass sooner into the province of the historian. The novels of Dickens will live longer, because they take hold of the permanent and universal sentiments of the race,—sentiments which pervade all classes, and which no culture can ever eradicate. His fun may be too boisterous for the refined tastes of his own time, or, for the matter of that, of posterity; his pathos may appear maudlin; but they carried everything before them when they first burst upon our literature, because, however much exaggerated, they were exaggerations of what our race feels in its inner heart; and unless culture in the future works a miracle, and carries its changes beneath the surface, we may be certain that Dickens will keep his hold.

If Dickens had been asked why his novels were likely to

live, he would probably have answered that it was because he put more work into them than any of his contemporaries. He was fond of insisting that genius meant attention. The definition may be accepted with a qualification. No man can become a genius by resolving to attend; but if he attends very much in some one direction by natural impulse, then he may be said to have a genius, whatever may be his field of work. No genius is of much avail for great literary productions without attention. Dickens could never have gathered together his amazing variety of characters and abundance of incidents without attention. M. Taine, in his criticism of Dickens, dwells much upon the boundless wealth of his imagination; Dickens himself would have expressed the same fact by speaking of the persistence and closeness of his attention. It comes to the same thing in the end, whichever way we express it; but there is no doubt that Dickens’s own expression is more descriptive of his actual method of work. M. Taine rather gives us the notion that Dickens sat down and trusted to the inexhaustible fertility of his imagination; whereas, ready and active as his imagination ever was, he accumulated materials for it with the industry of a pre-Raphaelite painter. The charm, the inimitable secret, lay, of course, in the transmitting process through which dry facts passed in his imagination; but he laboured earnestly, exercised the most painstaking attention, not merely in bringing his facts together, but in setting them, with all their superadded value, for his special purposes. Dickens would have been a humorist though he had never written a line; he could never have helped attending to the humorous side of whatever met his eye; but without the attention on which he prided himself as the secret of his power, he could never have established himself securely as one of the greatest humorists in literature.

Our Mutual Friend was published in 1861 and 1865. After an interval of five years, during which he contributed to three Christmas numbers of *All the Year Round*, and wrote *A Holiday Romance* and *George Silverman’s Explanation* for an American publisher, the first number of *The Mystery of Edwin Drood* was issued in April 1870. He did not live to complete the novel. For some years severe pains in the left hand and foot had given warning that he was overtaxing his system, but the warning was not fully understood till too late. He was suddenly overcome by a stroke, caused by effusion on the brain, on the evening of the 8th of June, and ceased to breathe on the following day. In his will he had desired that he should be buried in “an inexpensive, unostentatious, and strictly private manner, without any public announcement of the time or place of his burial.” These conditions were observed; but his executors did not consider them inconsistent with his receiving the honour of interment in Westminster Abbey, where he was buried on the 14th of June 1870.

His death took place at Gadshill Place, a house near the main road between Rochester and Gravesend, which he had bought in 1856, and which had been his home since 1859. Here he worked, and walked, and saw his friends, and was loved and almost worshipped by his poorer neighbours for miles around. His previous residences in London had been Furnival’s Inn, where fame found him a young man writing sketches for the *Chronicle*; 48 Doughty Street, after his marriage and first flood of success; Devonshire Terrace, from 1839 to 1851; Tavistock House, from 1851 to 1859. These residences were varied by his numerous excursions to provincial towns, to the Continent, to America. But “perhaps there was never a man who changed places so much and habits so little. He was always methodical and regular, and passed his life from day to day, divided for the most part between working

and walking, the same wherever he was " It is a notable feature in his regularity that it was never a complacent routine; it was persisted in in spite of restless longings which he never conquered to the last

The authorized life of Dickens is that by John Forster, 3 vols 8vo, 1871-2-4. There are two books on his public readings—*Charles Dickens as a Reader*, by Mr C Kent, and *Pen Photographs of his Readings in America*, by Miss Kate Field Mr G. A. Sala has published a valuable essay on his "Genius and Character." (W. M.)

DICOTYLEDONS. See **BOTANY**, vol. iv. p 92, &c., and **VEGETABLE KINGDOM**.

DICTATOR, the highest extraordinary magistrate of the ancient Roman republic. The original name of this office was *magister populi*, by which appellation he was called in the sacred books down to the latest times of the commonwealth.

When the republican form of government was established at Rome, and the supreme executive vested in the two consuls, emergencies sometimes occurred in which it seemed that the safety of the state might advantageously be intrusted for the time to some one man, whose past life had gained for him the esteem and respect of the whole body of the citizens. The idea of this office was borrowed by the Romans from the constitution of some of the Latin towns which they had subdued. It lay with the senate to decide when the services of a dictator were necessary. The power of nominating a man to the office was by that body made over to one of the consuls. It is not exactly determined to which of these officers the nomination of a dictator properly appertained.

The insignia of the dictator's office were—first, the lictors, twenty-four in number, who bore the fasces and secures; second, the curule chair; and third, the toga prætexta.

The first dictator was appointed at Rome 501 B C, nine years after the expulsion of the Tarquins. Who the first dictator was is differently stated by different historians, but it is most probable that it was T. Lartius.

Dictators were generally appointed to conduct a foreign war, but it often happened that in matters of less importance they were appointed with nominal authority. The dictator was generally selected in the absence of the consuls to perform some small ceremonies, which in strict propriety could only be gone through by one of the consuls. Thus he was sometimes chosen to hold the comitia, to appoint

holidays, to affix the *clavus annalis* in the temple of Jupiter, and to preside at trials. As soon as the dictator was appointed, he was required to select a master of the horse (*magister equitum*), whose term of office was the same as his own.

The power of the dictator was absolute; and so long as he remained in office no appeal was open against his mandates to any other authority in the state. He was nearly altogether independent of the senate. He could inflict much severer punishments than the consuls without being liable, as these officers were, to have his sentence reversed by the assembly of the people. His power was as irresponsible as it was absolute. In token of the absolute power of the dictators over the lives of their fellow-citizens, their lictors bore the axe in the midst of the fasces, even in their walks through the city—a mark of distinction which the consuls had formerly enjoyed, but which had been abolished in their case by the Valerian law.

Though the power of the dictator was thus great, it was nevertheless limited by certain indirect restrictions. The most important of these was, that he had no control whatever over the public money, and had to content himself with such sums as were allowed him by the senate. He was not allowed to leave Italy; and could not appear on horseback in the city without the express permission of the people. The surest safeguard, however, against any treacherous designs on the part of the dictator was the shortness of the period during which he remained in office. This was never permitted to exceed six months.

When a dictator was appointed, all the ordinary magistrates ceased to be directly responsible to the governing authorities of the state, and took their orders directly from him. The only magistrates exempt from this necessity were the tribunes of the commons. The inferior officers, however, did not, as has been supposed, retire from office altogether. They merely obeyed the dictator so long as he continued in power and on his resignation entered once more upon the untrammelled exercise of their authority.

It remains to be added that dictators were only appointed at Rome so long as Italy remained unsubdued. The last dictator appointed at Rome held office in 202 B C.; from that time the constitutional dictatorship disappears from Roman history.

See Mommsen's *Römische Staatsrecht*, ii. 1.

D I C T I O N A R Y

ALTHOUGH dictionaries are so numerous, so well known, and so much used, they vary so greatly in the nature and treatment of their subjects that any definition must be very much modified in order to include some works so entitled and usually so called. In its proper and most usual meaning, a dictionary is a book containing a collection of the words of a language, dialect, or subject, arranged alphabetically or in some other definite order, and with explanations in the same or some other language. What is essential is, that the words given should be all or most of those belonging to the subject of the dictionary, or at least be very many in number, and that they should be arranged in definite order, and accompanied with interpretations. Many other characters may rightly and advantageously belong to a dictionary, but these are the essentials. When the words are few in number, being only a small part of those belonging to the subject, or when they are given without explanation, or some only are explained, or the explanations are partial, the work is called a vocabulary. An alphabetical arrangement of the words of some book or author with references to the

places where they occur is called an index. When under each word the phrases containing it are added to the references, the work is called a concordance. Sometimes, however, these names are given to true dictionaries; thus the great Italian dictionary of the Academy of La Crusca, in six volumes folio, is called *Vocabolario*, and Ernesti's dictionary to Cicero is called *Index*. When the words are arranged according to a definite system of classification under heads and subdivisions, according to their nature or their meaning, the book is usually called a classed vocabulary; but when sufficient explanations are given, it is often accepted as a dictionary, like the *Onomasticon* of Julius Pollux, or the native dictionaries of Sanskrit, Manchn, and many other languages. Dictionaries were originally books of reference explaining the words of a language or of some part of it. As the names of things as well as those of persons and places, are words, and often require explanation even more than other classes of words, they were necessarily included in dictionaries, and often to a very great extent. In time, books were devoted to them alone, and were limited to special

subjects, and these have so multiplied, that dictionaries of things now rival in number and variety those of words or of languages, while they often far surpass them in bulk. There are dictionaries of biography and history, real and fictitious, general and special, relating to men of all countries, characters, and professions; dictionaries of bibliography, relating to all books, or to those of some particular kind or country, dictionaries of geography, of the whole world, of particular countries, or of small districts, of towns and of villages, of castles, monasteries, and other buildings. There are dictionaries of philosophy; of mathematics, of natural history, zoology, botany; of birds, trees, plants, and flowers; of chemistry, geology, and mineralogy; of architecture, painting, and music, of medicine, surgery, anatomy, pathology, and physiology; of diplomacy; of law, canon, civil, statutory, and criminal; of political and social sciences, of agriculture, rural economy, and gardening; of commerce, navigation, horsemanship, and the military art; of mechanics, machines, and the manual arts. There are dictionaries of antiquities, of chronology, of dates, of genealogy, of heraldry, of diplomatics, of abbreviations, of useful receipts, of monograms, of adulterations, and of very many other subjects. And lastly, there are dictionaries of the arts and sciences, and their comprehensive offspring, *encyclopædias*, which include in themselves every branch of knowledge. The tendency of dictionaries of language is to increase the vocabulary, to multiply articles, the tendencies of dictionaries of things, and especially of *encyclopædias*, is to diminish the number of articles, fusing subjects together as far as possible, and to develop the explanation, making it longer and more copious and circumstantial. This does away with the necessity of turning to many articles scattered through all parts of the work for a complete view of a subject. On the other hand, as requiring an index, it is less convenient for frequent reference on minor points.

Dictionarium is a word of low or modern Latinity;¹ *dictio*, from which it was formed, was used in mediæval Latin to mean a word. *Lexicon* is a corresponding word of Greek origin, meaning a book of or for words—a dictionary. A glossary is properly a collection of unusual or foreign words requiring explanation. It is the name frequently given to English dictionaries of dialects, which the Germans usually call *idioticon*, and the Italians *vocabolario*. *Wörterbuch*, a book of words, was first used among the Germans according to Grimm, by Kramer (1719), imitated from the Dutch *woordenboek*. From the Germans the Swedes and Danes adopted *ordbok*, *ordbog*. The Icelandic *ordabók*, like the German, contains the genitive plural. The Slavonic nations use *slovar*, *slovník*, and the Southern Slavs *ryetshnik*, from *slovo*, *ryetsh*, a word, formed, like dictionary and lexicon, without composition. Many other names have been given to dictionaries, as *thesaurus*, *Sprachschatz*, *cornucopia*, *gazo-phylacium*, *comprehensorium*, *catholicon*, to indicate their completeness, *manipulus predicantium*, *promptorium puerorum*, *liber memorialis*, *hortus vocabulorum*, *ionia* (a violet bed), *alveary* (a beehive), *kamoos* (the sea), *haft kulzum* (the seven seas), *tsze tien* (a standard of character), *onomasticon*, *nomenclator*, *bibliotheca*, *elucidario*, *Mundart*, *Sammlung*, *clavis*, *scala*, *pharetra*,² *La*

Crusca from the great Italian dictionary, and *Calepino* (in Spanish and Italian) from the Latin dictionary of Calepino.

A dictionary of language should contain all the words which may be reasonably looked for in it, so arranged as to be readily and surely found, and so explained as to make their meaning, and if possible their use, clear to those who have a competent knowledge of the language or languages in which the explanations are given. Some dictionaries may suppose a very considerable degree of knowledge in those who use them, but though one could not be written which would make every word clear to a young child, they should in general be as easy and simple as possible. A full and complete dictionary of a great literary language can be compiled only by great labour, patience, knowledge, and skill, employed for many years in collecting, correcting, adjusting, and completing the labours of many previous generations of workers. Such a dictionary should include all the words of the language. As a great library cannot select books and publications, but must collect and preserve all without regard to their apparent value or worthlessness, for it is impossible to foretell what may be valued in future times, or what may be required by its readers for completing their researches, so a complete and standard dictionary should make no choice. Words obsolete and newly coined, barbarous, vulgar, and affected, temporary, provincial, and local, belonging to peculiar classes, professions, pursuits, and trades, should all find their place,—the only question being as to the evidence for their existence,—not indeed, all received with equal honour and regard, but with their characteristics and defects duly noted and pointed out. A complete dictionary should be the complete record and picture, or, as Archbishop Trench says, the inventory of language. It must contain all words ever in any way belonging to it, in writing or in speech, or it will not be a complete record, and will not satisfy those who consult it. Lexicographers have too often tried to exercise a choice, and not content with being recorders, have made themselves judges of words, and refiners and improvers of language, and have attempted not only to reform the language, but to check it in that growth and development which is inherent in all living tongues, and to make their dictionaries standards and rules of language, rather than inventories and records. Unfortunately, this error is echoed by popular opinion, and a standard dictionary is too often supposed to be an arbitrator of words, rather than a standard of excellence among dictionaries. The intention of the author should be, as Beseherelle says, not to reform the language, but to present it with all its caprices, anomalies, irregularities, beauties, defects,—in a word, as the nation has made it. The precise value or worthlessness of a word can only be marked when it is admitted. If not found in the dictionary, it may be supposed to have been unknown to the author, as there is nothing to show that it has been condemned and rejected. The French Academy at first rejected all technical terms, but was compelled by popular clamour and the success of *Fréretière's* dictionary, in which very many were given, to admit them in increasing numbers in its second and all subsequent editions. It is the more necessary that they should not be excluded, as the meanings are difficult to learn, and are most often looked for; and a dictionary intended for general use, should, as Dr Johnson says, include the words belonging to every profession. Obsolete words are admitted by Johnson, Latré, and other first-rate lexicographers, only when they have remained in use

¹ Joannes de Garlandia, who probably was born about 1275, and died soon after 1250, gives the following explanation in his *Dictionarius*, which is a classical vocabulary—"Dictionarius dicitur libellus sive a dictionibus magnis necessarius, quas tenetur quilibet scolarius, non tantum in cernio de lignis factis, sed in cordis armariolo firmatur retinere." This has been supposed to be the first use of the word

² An excellent dictionary of quotations, perhaps the first of the kind; a large folio volume printed in Strasburg about 1475, is

entitled "*Pharetra auctoritates et dicta doctorum, philosophorum, et poetarum continens.*"

after a certain period. Richardson gives only those useful for etymology, which is Littré's rule for patois. Grimm admits all words at any time belonging to High German or its dialects. The great German dictionaries generally admit dialects, and in this respect are more complete than the French and English. The Chinese give in their standard dictionaries every character known to exist, though many are erroneous, corrupt, vulgar, or local, or are merely improvements proposed by some eminent person. Of the ancient characters, sometimes the pronunciation, and occasionally the meaning, are unknown, while both one and the other are in some cases completely lost. Johnson omits all words relating to proper names, but they, as well as proper names, often as really belong to a language as any other words. The Philological Society propose that their new dictionary of English, begun in 1856, shall contain "every word occurring in the literature of the language," and "admit as authorities all English books," unwisely excepting "such as are devoted to purely scientific subjects, as treatises on electricity, mathematics," &c., beginning "with that definite appearance of an English type of language distinct from the preceding semi-Saxon," about the year 1250. Their vocabulary of words beginning with the letter B, printed in 1863, contains 17,729. The practice of universal admission of words is becoming more generally adopted in standard dictionaries of all languages.

Words can be most surely and quickly found when arranged alphabetically in a single series. Other arrangements, though sometimes more useful, are not so generally convenient. When it is thought desirable to separate any class of words, they should still be also inserted in their proper places in the general alphabet. In a large dictionary a small separate additional alphabet is almost lost, and is usually overlooked by searchers. According to Grimm, the alphabetical arrangement not only facilitates reference, but makes the author's work quicker and surer, "for he who would insert rich contributions must have the places for them before his eyes, and not have to search about undecidedly to find whether the word is already there or not." The order of the alphabet should be that commonly used in the language. Any other makes reference more slow and uncertain. Grimm says that the order of the Sanskrit alphabet, adopted by Diefenbach and others, brings confusion rather than light to European languages. The etymological arrangement under roots has been generally condemned by experience. It places all words of the same origin together, so that they can be at once seen, which is often very useful and important, and is a great help in learning a language, as it assists the memory. But a word not belonging to the small number of roots cannot be found unless its root is known; otherwise it must be looked for in the index, or if there is none, sought for by guess-work in many places. And as etymologies will vary according to fancy or knowledge, no word, as Grimm says, will be sure of its place, and no arrangement is more destructive of the object and use of a dictionary. All its advantages may be secured by giving under each root a list of derivatives. Another system, more rarely adopted, though perhaps more useful, is that of arranging all words under their leading ideas, so that all those relating to a subject are seen together, and the proper word to express an idea may be found almost as easily as the idea expressed by a word may be found in an ordinary dictionary. It is, in fact, a classed vocabulary of all the words of the language, with the sections arranged alphabetically, and resembles in its purpose the classified index of a bibliographical dictionary, while it is quite as useful and necessary. Boissière has chosen about 2000 common words, under each of which he gives all the

French words evidently attached to it by community of ideas, or by relations of habitual use, cause, means, effect, or any analogy whatever. This part, he says, shows how to call things by their right names, and, as he remarks, great care is taken to teach children grammar, but none to teach them words. In the upper part of each page he gives all the words in alphabetical order, with a reference to the group in which each will be found. Roget, in his *Thesaurus*, gives under each head (1000 in number) not only the words belonging to the idea, but their opposites, and adds at the end of the book an index of all the words. This system, on account of its very great use and value, might well be made a subsidiary part of a standard dictionary, the groups being placed in the general alphabet, and a reference to each group being added to each word. The arrangement by terminations is of use grammatically and stenographically, and for making out words of which the beginning is illegible or wanting. A dictionary of rhymes is similar, but not exactly the same, and is of little use except for making verses, and, when the rhymes are perfect, for showing the pronunciation. In the Semitic languages words are commonly placed under their roots, and in MS. lexicons the roots are often arranged alphabetically, according to the last radical. When Lane was making his great Arabic lexicon, he generally had before him eight or ten native lexicons, containing three different arrangements of roots. In Chinese dictionaries the characters are usually arranged under the 214 radicals, which now serve as an alphabet. In former times the number varied, and was much greater. The characters under each radical are further subdivided according to the number of strokes used in making each character, in addition to its radical, or the abbreviation of its radical which each character contains. But no arrangement is attempted of the characters having the same number of strokes. Other systems are sometimes used, arranged by tones and endings, and by the characters (about 1040) called phonetics.

In the separate articles of a dictionary the arrangement must vary very much with the language, as well as with the word itself. When necessary, the orthography, pronunciation, and grammatical inflexions of the word should be given, and any variations of these at different times and places carefully pointed out, as well as the character of the word, such as obsolete, provincial, &c., and forms beginning with a different spelling should be placed in separate articles, with references to the main article. The etymology should be given, referring derivatives to their respective roots; and under each root giving, if not the derivation as far back as it can be traced, at least what Littré calls the secondary etymology—that is, deriving it from a word not belonging to the language, as when a French word is traced to a Latin or German word without proceeding farther; and cognate words should generally be enumerated, often with their principal meanings. This gives a primary meaning, but care must be taken that the derivation is a real one, not a mere fancy or guess. The times when the word was introduced or became obsolete should be noted, and the meaning it bore at first, as well as those which prevailed at various periods. The meanings may be arranged in a series, not merely as they may be imagined to have been logically developed from each other, but as their connection may be traced, and can be shown to have existed in actual use, and where this connection cannot be traced, the defect should be pointed out. Sometimes, too, the meanings are, as Johnson says, collateral. In some kinds of dictionaries the explanations may be merely sufficient to identify the word, as in Bilderdyk's *Voordenboek voor de Nederdutsche Spelling*, or, as in most small dictionaries, they may merely give the sense. They may also be full

Under either system, Arabic, Persian, and Turkish, whose dictionaries are so closely connected, would be widely separated. A wholly geographical arrangement would be inconvenient, especially in Europe. Any system, however, which attempts to arrange in a consecutive series the great network of languages by which the whole world is enclosed, must be open to some objections; and the arrangement adopted in this list has produced some anomalies and dispersions which might cause inconvenience if not pointed out. The old Italic languages are placed under Latin, all dialects of France under French (but Provençal as a distinct language), and Wallachian among Romanic languages. Low German and its dialects are not separated from High German. Basque is placed after Celtic, Albanian, Gipsy, and Turkish at the end of Europe, the last being thus separated from its dialects and congeners in Northern and Central Asia, among which are placed the Kazan dialect of Tartar, Samoyed, and Ostiak. Accadian is placed after Assyrian among the Semitic languages, and Maltese as a dialect of Arabic; while the Ethiopic is among African languages, as it seemed undesirable to separate it from the other Abyssinian languages, or these from their neighbours to the north and south. Circassian and Ossetic are joined to the first group of Aryan languages lying to the north-west of Persia, and containing Armenian, Georgian, and Kurd. The following is the order of the groups, some of the more important languages, that is, of those best provided with dictionaries, standing alone—

EUROPE: Greek, Latin, French, Romance, Scandinavian, Teutonic (including English and German), Celtic, Lithuanic, Slavonic, Ugrian, Turkish.

ASIA: Semitic, Armenian, Persian, Sanskrit, Indian, Indo-Chinese, Indian Archipelago, Philippines, Chinese, Japanese, Northern and Central Asia.

AFRICA: Egypt and Abyssinia, Eastern Africa, Southern, Western, Central, Berber.

Australia and Polynesia.

AMERICA: North, Central (with Mexico), South.

EUROPE.

Greek.—Athenæus quotes 35 writers of works, known or supposed to be dictionaries, for, as they are all lost, it is often difficult to decide on their nature. Of these, Antichides, who lived after the reign of Alexander the Great, wrote *Ἑλληνικὸς*, which seems to have been a sort of dictionary, perhaps explaining the words and phrases occurring in ancient stories. Zenodotus, the first superintendent of the great library of Alexandria, who lived in the reigns of Ptolemy I and Ptolemy II, wrote *Γλῶσσαι*, and also *Λέξεις ἑθνικαί*, a dictionary of barbarous or foreign phrases. Aristophanes of Byzantium, son of Apelles the painter, who lived in the reigns of Ptolemy II. and Ptolemy III, and had the supreme management of the Alexandrian library, wrote a number of works, as *Ἀττικαὶ Λέξεις*, *Λακονικαὶ Γλῶσσαι*, which, from the titles, should be dictionaries, but a fragment of his *Λέξεις*, printed by Boissonade, in his edition of Herodian (London, 1869, 8vo, pp. 181–9), is not alphabetical. Artemidorus, a pupil of Aristophanes, wrote a dictionary of technical terms used in cookery. Nicander Colophonius, hereditary priest of Apollo Clarius, born at Claros, near Colophon, in Ionia, probably in reputation for 50 years, from 181 to 135, wrote *Γλῶσσαι* in at least three books. Parthenius, a pupil of the Alexandrian grammarian Dionysius (who lived in the 1st century before Christ), wrote on choice words used by historians. Didymus, called *χαλκέντερος*, who, according to Athenæus, wrote 3500 books, and, according to Seneca, 4000, wrote lexicons of the tragic poets (of which book 28 is quoted), of the comic poets, of ambiguous words, and of corrupt expressions. Glossaries of Attic words were written by Crates, Philemon, Philotas, and Theodorus, of Cretan, by Hermon or Hermonax; of Phrygian, by Neoptolemus, of Rhodian, by Moschus, of Italian, by Diodorus of Tarsus, of foreign words, by Silenus; of synonyms, by Simaristus; of cookery, by Heraclion, and of drinking vessels, by Apollodorus of Cyrene. According to Suidas, the most ancient Greek lexicographer was Apollonius the sophist, son of Archibius. According to the common opinion, he lived in the time of Augustus at Alexandria. He composed a lexicon of words used by Homer, *Λέξεις Ὅμηρικαί*, a very

valuable and useful work, though much interpolated, edited by Villosion, from an MS. of the 10th century, Paris, 1773, 4to, 2 vols; and by Tollus, Leyden, 1788, 8vo; ed. Bekker, Berlin, 1833, 8vo. Erotian or Herodian, physician to Nero, wrote a lexicon on Hippocrates, arranged in alphabetical order, probably by some copyist, whom Klein calls for “*homo sciolus*.” It was first published in Greek in H. Stephani *Dictionarium Medicum*, Paris, 1564, 8vo, ed. Klein, Lipsia, 1865, 8vo, with additional fragments. Timæus the sophist, who, according to Ruhnken, lived in the 3d century, wrote a very short lexicon to Plato, which, though much interpolated, is of great value, 1st ed. Ruhnken, Leyden, 1754, ed. locupletior, Lugd. Bat. 1789, 8vo. Ælius Mæris, called the Atticist, lived about A.D. 190, and wrote an Attic and Greek lexicon, 1st ed. Hudson, Oxf. 1712, 8vo. Julius Pollux (*Ἰούλιος Πολυδεύκης*) of Nancratis, in Egypt, died, aged 58, in the reign of Commodus (180–192), who made him professor of rhetoric at Athens. He wrote, besides other lost works, an *Onomasticon* in ten books, being a classed vocabulary, intended to supply all the words required by each subject with the usage of the best authors. It is of the greatest value for the knowledge both of language and antiquities. First printed by Aldus, Venice, 1500, fol; often afterwards, ed. Lederlinus and Hemsterhus, Amst. 1706, fol. 2 vols, ed. Dindorf, Leip. 1824, 8vo, 5 vols. Harpocration of Alexandria, who lived in the 4th century, wrote a lexicon on the ten Attic orators, first printed by Aldus, Ven. 1503, fol., ed. Dindorf, Oxford, 1853, 8vo, 2 vols from 14 MSS. Orion, a grammarian of Thebes, in Egypt, who lived between 390 and 460, wrote an etymological dictionary, printed by Sturz, Leipzig, 1820, 4to. Helladius, a priest of Jupiter at Alexandria, when the heathen temples there were destroyed by Theophilus in 389 or 391 escaped to Constantinople, where he was living in 408. He wrote an alphabetical lexicon, now lost, chiefly of prose, called by Photius the largest (*πολυστιχάτατον*) which he knew. Ammonius, professor of grammar at Alexandria, and priest of the Egyptian ape, fled to Constantinople with Helladius, and wrote a dictionary of words similar in sound but different in meaning, which has been often printed in Greek lexicons, as Aldus, 1497, Stephanus, and separately by Valckenacr, Lugd. Bat. 1739, 4to, 2 vols, and by others. Zenodotus wrote on the cries of animals, printed in Valckenacr’s *Ammonius*; with this may be compared the work of Vincentio Carlucci, *Lexicon totum quæ a brutis animalibus emittuntur*, Perusia, 1779, 12mo. Hesychius of Alexandria, probably a heathen, who lived before 389, wrote a lexicon, important for the knowledge of the language and literature, containing many dialectic and local expressions and quotations from other authors, 1st ed. Aldus, Ven. 1514, fol., the best is Alberti and Ruhnken, Lugd. Bat. 1746–66, fol. 2 vols., collated with the MS. in St Mark’s Library, Venice, the only MS. existing, by Niels Iversen Schow, Leipzig, 1792, 8vo, ed. Schmidt, Jena, 1867, 8vo. The foundation of this lexicon is supposed to have been that of Pamphilus, an Alexandrian grammarian, quoted by Athenæus, which, according to Suidas, was in 95 books from E to Ω; A to Δ had been compiled by Zopiron. Photius, consecrated patriarch of Constantinople, 25th Dec. 857, living in 886, left a lexicon, partly extant, and printed with Zonaras, Lips. 1808, 4to, 3 vols., being vol. iii.; ed. Naber, Leidæ, 1864–5, 8vo, 2 vols. The most celebrated of the Greek glossaries is that of Suidas, of whom nothing is known. He probably lived in the 10th century. His lexicon is an alphabetical dictionary of words, including the names of persons and places,—a compilation of extracts from Greek writers, grammarians, scholiasts, and lexicographers, very carelessly and unequally executed. It was first printed by Demetrius Chalcondylas, Milan, 1499, fol., the best edition, Bernhardt, Halle, 1853, 4to, 2 vols. John Zonaras, a celebrated Byzantine historian and theologian, who lived in the 12th century, compiled a lexicon, first printed by Tittmann, Lips. 1808, 4to, 2 vols. An anonymous Greek glossary, entitled *Ἑτυμολογικὸν μέγα*, *Etymologicum magnum*, has been frequently printed. The first edition is by Musurus, Venetia, 1499, fol.; the best by Gaisford, Oxonii, 1848, fol. It contains many grammatical remarks by famous authorities, many passages of authors, and mythological and historical notices. The MSS. vary so much that they look like the works of different authors. Eudocia Augusta of Makrembolis, wife of the emperors Constantine XI and Romanus IV. (1059 to 1071), compiled a dictionary of history and mythology, called *Ἱερίδ* (bed of violets), first printed by D’Ansse de Villosion, *Anecdota Græca*, Venetia, 1781, 4to, vol. i. pp. 1–442. It was supposed to have been of much value before it was published. Thomas, Magister Officiorum under Andronicus Palæologus, afterward called as a monk Theodulus, wrote *Ἑταυρολογικὸν Ἀττικῶν*, printed by Calbergus, Romæ, 1817, 8vo. Papias, *Vocabularium*, Mediolani, 1476, fol. Craston, an Italian Carmelite monk of Piacenza, compiled a Greek and Latin lexicon, edited by Bonns Accursius, printed at Milan, 1478, fol.; Aldus, Venetia, 1497, fol. Guarino born about 1450 at Favara, near Camarino, who called himself both Phavorinus and Camers, published his *Thesaurus* in 1504. These three lexicons were frequently reprinted. Estienne, *Thesaurus*, Geneva, 1572 fol. 4 vols; ed. Valpy, Lond. 1816–26, 8 vols. fol.; Paris, 1831–65

9 vols fol 9902 pages *Kιβωτος*, the ark, was intended to give the whole language, ancient and modern, but vol. 1, Constantinople, 1819, fol. 763 pages A to A, only appeared, as the publication was put an end to by the events of 1821. **ENGLISH**—Jones, London, 1823, 8vo; Dunbar, Edin. 3d ed. 1850, 4to Liddell and Scott, 6th ed. 1618, 4to. Richelet, Genève, 1680, fol. 2 vols; od. Gattel, Paris, 1840, 8vo, 2 vols

The French Academy, after five years' consideration, began their dictionary, 7th February 1639, by examining the letter A, which took them nine months to go through. The word *Académie* was for some time omitted by oversight. They decided, 8th March 1638, not to cite authorities, and they have since always claimed the right of making their own examples. Olivier justifies them by saying that for eighty years all the best writers belonged to their body, and they could not be expected to cite each other. Their design was to raise the language to its last perfection, and to open a road to reach the highest eloquence. Antoine Furetière, one of their members, compiled a dictionary which he says cost him forty years' labour for ten hours a day, and the manuscript filled fifteen chests. He gave words of all kinds, especially technical, names of persons and places, and phrases. As a specimen, he published his *Essai*, Paris, 1684, 4to, Amst 1685, 12mo. The Academy charged him with using the materials they had prepared for their dictionary, and expelled him, 22d January 1685, for plagiarism. He died 14th May 1688, in the midst of the consequent controversy and law suit. His complete work was published, with a preface by Bayle, La Haye and Rotterdam, 1690, fol. 3 vols, again edited by Basnage de Beauval, 1701, La Haye, 1707, fol. 4 vols. From the edition of 1701 the so-called very popular *Dictionnaire de Trevoux*, Trevoux, 1704, fol. 2 vols., was made by the Jesuits, who excluded everything that seemed to favour the Calvinism of Basnage. The last of its many editions is Paris, 1771, fol. 8 vols. The Academy's dictionary was first printed Paris, 1694, fol. 2 vols. They began the revision in 1700, second edition 1718, fol. 2 vols; 3d, 1740, fol. 2 vols, 6th, 1835, 2 vols. 4to, reprinted 1855, Supplément, by F. Raymond, 1836, 4to, Complément, 1842, 4to, reprinted 1856, *Dictionnaire Historique*, Paris, 1858-65, 4to, 2 parts (A to Actu), 795 pages, published by the Institut Dochez, Paris, 1859, 4to. Bescherelle, *ib* 1844, 4to, 2 vols., 5th ed. Paris, 1857, 4to, 2 vols., 1865 Landais, Paris, 1835, 12th ed. *ib* 1854, 4to, 2 vols. Littré, Paris, 1863-73, 4to, 4 vols 7118 pages, Supplément, Paris, 1877, 4to, to be about 12 parts (parts i-v 200 pages). Phœnician.—M A Levy, Breslau, 1864, 8vo Samaritan.—Crusius, Altdorphi, 1613, 4to Morini, Parisus. 1657, 12mo. Hilligerus, Witteberge, 1679, 4to Cellarius, Cizae, 1682, 4to; Frankof 1705 Uheimann, Lipsue, 1837, 8vo Nicholls, London, 1859, 8vo

Assyrian.—Norris, London, 1868, 8vo, 3 vols PROPER NAMES — Menant, Paris, 1861, 8vo

Accadian — Lenormant, Paris, 1875, 8vo

Syriac — Joshua ben Ali, a physician, who lived about 885, made a Syro-Arabic lexicon, of which there is an MS in the Vatican Hoffmann printed this lexicon from Alif to Mim, from a Gothic MS, Kiel, 1874, 4to Jeshna bar Babilul, living 963, wrote another, great part of which Castelli put into his lexicon His MS is now at Cambridge, and, with those at Florence and Oxford, was used by Bernstein. Elias bar Shunayn, born 975, metropolitan of Nisibis, 1009, wrote a Syriac and Arabic lexicon, entitled *Kutáb ul Tarjuman fi Taalem Loghat es Sárán* (Book called the Interpreter for teaching the Language of the Syrians), of which there is a MS in the British Museum It was translated into Latin by Thomas à Novaria, a Minorite friar, edited by Germanus, and published at Rome by Obseius, 1636, 8vo It is a classified vocabulary, divided in 30 chapters, each containing several sections Crusius, Witteberge, 1612, 4to Buxtorf, Basilee, 1622, 4to Ferrarius, Rome, 1622, 4to Trost, Cothenis Anhaltor 1643, 4to Gntbir, Hamburg, 1667, 8vo Schaaf, Jugl Bat 1708, 4to Zanolini, Patavia, 1742, 4to Castellus, ed Michælis Gottingen, 1788, 4to, 2 vols. Bernstein, Berlin, 1857, &c fol Smith (Robt Paine), Dean of Canterbury, Oxon, 1868, &c fol. fane 1-3 contain 538 pages Zingerle, Rome, 1873, 8vo, 148 pages

Arabic — The native lexicons are very many, voluminous, and copious In the preface to his great Arabic-English lexicon, Lane describes 33, the most remarkable of which are—the *Eym*, so called from the letter which begins its alphabet, commonly ascribed to El Khaleel, (who died before A H 175 [A D 791], aged 74 the *Sihah* of El Jowharce (died 398 [1003]) the *Mohkam* of Ibn Seccah the Andalusian, who was blind, and died A H 458 [A D 1066], aged about 60 the *Asas* of Ez Zamakbsharee (born 467 [1075], died 538 [1144]), “a most excellent repository of choice words and phrases” the *Lisán el Arab* of Ibn Mnkarram (born 630 [1232], died 711 [1311]), Lane’s copy is in 28 vols 4to the *Kamoos* (The Sea) of El Feroezábadee (born 729 [1328], died 816 [1413]) the *Tay el Aroos*, by Murtada Ez Zebadee (born A D 1732, died 1791)—the copy made for Lane is in 24 vols thick 4to The *Sihah* was printed Hardervici Getorum, 1774, 4to, Bulak, 1865, fol 2 vols *Kamoos*, Calcutta, 1817, fol 2 vols, Bombay, 1855, fol 920 pages *Sirr el Lagal*, by Farish esh Shidiac, Tunis, fol 609 pages *Muheet al Muheet*, by Beirrus Al Bustance, Beyrout, 1867-70, 2 vols 4to, 2358 pages (abridged as *Katr Al Muheet*, *ib* 1867-69, 2 vols 8vo, 2352 pages), is excellent for spoken Arabic PERSIAN — The *Soorah*, by Juma, Calcutta, 1812-15, 2 vols 4to *Samachsharu Lexicon*, ed Wetzstein, Leipz 1845, 4to; 1850 *Muntakhal al Loghat*, Calcutta, 1808, *ib* 1836, Lucknow, 1845, Bombay, 1862, 8vo, 2 vols *Muntaha l Arabi*, 4 vols. fol 1840. *Shams al Loghat*, Bombay, 1860, fol 2 vols 509 pages TURKISH — *Achleri Kabir*, Constantinople, 1827, fol *El Kamoos*, *ib* 1816, fol 3 vols, translated by Acan Effendi, Boulae, 1835, fol 3 vols: *El Sihah*, translated by Al Vani, Constantinople, 1728, fol 2 vols, 1755-56, Sentari, 1802, fol 2 vols. LATIN — Raphelengus,

London, 1613, fol. Giggeus, Mediolani, 1632, fol 4 vols.: Gohus, Lugd. Bat. 1653, fol. (the best except Lane's). Jahn, Vindobonæ, 1802, 8vo. Freytag, Halle, 1830-38, 4 vols. 4to, abridged, *ib* 1837, 4to ENGLISH — Catafago (Arab-Eng and Eng-Arab), London, 1858, 8vo, 2 vols.; 2d ed. 1873, 8vo. Lane, London, 1863-74, fol book 1. parts 1-v. 2218 pages. The Arabic title is *Medd el Kamoos*, meaning either The Flow of the Sea, or The Extension of the Kamoos. It was undertaken in 1842, at the suggestion and at the cost of the late duke of Northumberland, then Lord Prudhoe, by Mr Lane, who returned to Egypt for the purpose, and lived in Cairo for seven years to study, and obtain copies of, the great MS lexicons in the libraries of the mosques, few of which had ever been seen by a European, and which were so quickly disappearing through decay, carelessness, and theft, that the means of composing such a work would not long have existed. His work is divided into two books, the first, to be completed in 8 parts, containing words and meanings commonly known to learned Arabs; the second, those that are of rare occurrence, and not commonly known. It does not contain proper names or modern words. The publication, interrupted by his death, will be carried on by his nephew, Mr Stanley Lane Poole. The preface to Part vi., now in the press, will state fully how far Mr Lane had advanced in this work, and what materials he has left for continuing it. Dr Badger is preparing an English-Arabic dictionary of at least 1000 pages 4to, which will be very useful when finished. Newman (modern), *ib* 1872, 8vo, 2 vols 856 pages FRENCH — Ruphy (Fr.-Ar.), Paris, 1802, 4to Bochter (do), Paris, 1828, 4to, 2 vols., 2d ed. *ib* 1850 Roland de Bussy (Algers, Fr.-Ar.) Noceda and San Lúcar, Manila, 1754, fol., 1832

Chinese.—Native Dictionaries are very numerous. Many are very copious and voluminous, and have passed through many editions. *Shwo wan*, by Hu Shin, is a collection of the ancient characters, about 10,000 in number, arranged under 540 radicals, published n.c. 150, usually in 12 vols. *Yu pien*, by Ku Ye Wang, published a. n. 530, arranged under 542 radicals, is the basis of the Chinese Japanese dictionaries used in Japan: *Ping tsou lou pien*, Pekin, 1726, 8vo, 130 vols: *Pei wan yün fu* (Thesaurus of Literary Phrases), 1711, 131 vols, 8vo, prepared by 66 doctors of the Han lin Academy in 7 years. It contains 10,362 characters, and countless combinations of two, three, or four characters, forming compound words and idioms, with numerous and copious quotations. According to Williams (*On the word Shin*, p. 79), an English translation would fill 140 volumes octavo of 1000 pages each. *Kanghi tsze tien* (Kanghi's Standard or Canon of the Character), the dictionary of Kanghi, the first emperor of the present dynasty, was composed by 30 members of the Han lin, and published in 1716, 40 vols. 4to, with a preface by the emperor. It contains 49,030 characters, arranged under the 214 radicals. It is generally in 12 vols, and is universally used in China, being the standard authority among native scholars for the readings as well as the meanings of characters. LATIN.—De Guignes (French, Lat.), Paris, 1813, fol.; Klaproth, Supplément, 1819; ed. Bazil, (Latin), Hong-kong, 1858, 4to. DICTYS CRETENSIS, one of the early historians from whom the later Roman grammarians imagined that Homer derived materials for the *Iliad* and *Odyssey*. According to an introduction prefixed by an unknown writer to the Latin translation entitled *Dictys Cretensis de Bello Trojano*, the author followed Idomeneus, king of Crete, in the Trojan war; and the MS of his work, written in Phœnician characters, was found in his tomb at Gnosus at the time of the occurrence of an earthquake in the thirteenth year of Nero's reign, and translated into Greek by order of that prince. A Latin version of the first five books has alone come down to us; but this is generally regarded as a forgery. There is little doubt, however, that there was a Greek original which was probably composed about the time of Nero. The main interest of the work consists in the fact that, along with that of Dares (q.v.), it was the source from which the Homeric legends were introduced into the romantic literature of the Middle Ages. The *editio princeps* dates as far back as 1470. The work is now usually printed along with that of Dares. The best editions are those of Perizonius and Dederich (Bonu, 1837).

DIDEROT, DENIS (1713-1784), one of the most active and original of the famous group of men of letters in France in the middle of the 18th century. He was born at Langres in 1713; he was educated by the Jesuits, like most of those who afterwards became the bitterest enemies of Catholicism, and, when his education was at an end, he vexed his brave and worthy father's heart by turning away from respectable callings, like law or medicine, and throwing himself into the vagabond life of a bookseller's hack in Paris. An imprudent marriage (1743) did not better his position. His wife was a devout Catholic, but her piety did not restrain a narrow and fretful temper, and Diderot's domestic life was irregular and unhappy. He sought consolation for chagrins at home in attachments abroad, first with a Madame Puisieux, a fifth-rate female scribbler, and then with Mdlle Voland, to whom he was constant for the rest of her life. His letters to her are among the most graphic of all the pictures that we have of the daily life of the philosophic circle in Paris. An interesting contrast may be made between the Bohemianism of the famous literary set who supped at the Turk's Head with the Tory Johnson and the Conservative Burke for their oracles, and the Bohemianism of the set who about the same time dined once a week at the Baron D'Holbach's, to listen to the

wild sallies and the inspiring declamations of Diderot. For Diderot was not a great writer, he stands out as a fertile, suggestive, and daring thinker, and a prodigious and most eloquent talker.

Diderot's earliest writings were of as little importance as Goldsmith's *Enquiry into the State of Polite Learning* or Burke's *Abridgement of English History*. He earned 100 crowns by translating Stanyan's *History of Greece*; with two colleagues he produced a translation of James's *Dictionary of Medicine*; and about the same date (1745) he published a free rendering of Shaftesbury's *Inquiry Concerning Virtue and Merit*, with some original notes of his own. With strange and characteristic versatility, he turned from ethical speculation to the composition of a volume of stories, which are gross without liveliness, and impure without wit. In later years he repented of this shameless work, just as Boccaccio is said in the day of his gray hairs to have thought of the sprightliness of the *Decameron* with strong remorse. From tales Diderot went back to the more congenial region of philosophy. Between the morning of Good Friday and the evening of Easter Monday he wrote the *Philosophic Thoughts* (1746), and he presently added to this a short complementary essay *On the Sufficiency of Natural Religion*. The gist of these performances is to press the ordinary rationalistic objections to a supernatural revelation; but though Diderot did not at this time pass out into the wilderness beyond natural religion, yet there are signs that he accepted that less as a positive doctrine, resting on grounds of its own, than as a convenient point of attack against Christianity. In 1747 he wrote the *Sceptic's Walk*, a rather poor allegory—pointing first to the extravagances of Catholicism; second, to the vanity of the pleasures of that world which is the rival of the church; and third, to the desperate and unfathomable uncertainty of the philosophy which professes to be so high above both church and world.

Diderot's next piece was what first introduced him to the world as an original thinker, his famous *Letter on the Blind* (1749). The immediate object of this short but pithy writing was to show the dependence of men's ideas on their five senses. It considers the case of the intellect deprived of the aid of one of the senses; and in a second piece, published afterwards, Diderot considered the case of a similar deprivation in the deaf and dumb. The *Letter on Deaf-Mutes*, however, is substantially a digressive examination of some points in aesthetics. The philoso-

phic significance of the two essays is in the advance they make towards the principle of Relativity. But what interested the militant philosophers of that day was an episodic application of the principle of relativity to the master-conception of God. What makes the *Letter on the Blind* interesting at the present moment is its presentation, in a distinct though undigested form, of the modern theory of variability, and of survival by superior adaptation. It is worth noticing, too, as an illustration of the comprehensive freedom with which Diderot felt his way round any subject that he approached, that in this theoretic essay he suggests the possibility of teaching the blind to read through the sense of touch. If the *Letter on the Blind* introduced Diderot into the worshipful company of the philosophers, it also introduced him to the penalties of philosophy. His speculation was too hardy for the authorities, and he was thrown into the prison of Vincennes. Here he remained for three months, then he was released, to enter upon the gigantic undertaking of his life.

A certain bookseller had applied to him with a project for the translation into French of Ephraim Chambers's *Cyclopædia*. Diderot accepted the proposal, but in his busy and pregnant intelligence the scheme became transformed. Instead of a mere reproduction of Chambers, he persuaded the bookseller to enter upon a new work, which should collect under one roof all the active writers, all the new ideas, all the new knowledge, that were then moving the cultivated class to its depths, but still were comparatively ineffectual by reason of their dispersion. His enthusiasm infected the publishers; they collected a sufficient capital for a vaster enterprise than they had at first planned; D'Alembert was persuaded to become Diderot's colleague; the requisite permission was procured from the Government; in 1750 an elaborate prospectus announced the project to a delighted public; and in 1751 the first volume was given to the world. The last of the letter-press was issued in 1765, but it was 1772 before the subscribers received the final volumes of the plates. These twenty years were to Diderot years not merely of incessant drudgery, but of harassing persecution, of sufferings from the cabals of enemies, and of injury from the desertion of friends. The ecclesiastical party detested the *Encyclopædia*, in which they saw a rising stronghold for their philosophic enemies. By 1757 they could endure the sight no longer. The subscribers had grown from 2000 to 4000, and this was a right measure of the growth of the work in popular influence and power. To any one who turns over the pages of these redoubtable volumes now, it seems surprising that their doctrines should have stirred such portentous alarm. There is no atheism, no overt attack on any of the cardinal mysteries of the faith, no direct denunciation even of the notorious abuses of the church. Yet we feel that the atmosphere of the book may well have been displeasing to authorities who had not yet learnt to encounter the modern spirit on equal terms. The *Encyclopædia* takes for granted the justice of religious tolerance and speculative freedom. It asserts in distinct tones the democratic doctrine that it is the common people in a nation whose lot ought to be the main concern of the nation's government. From beginning to end it is one unbroken process of exaltation of scientific knowledge on the one hand, and pacific industry on the other. All these things were odious to the old governing classes of France, their spirit was absolutist, ecclesiastical, and military. Perhaps the most alarming thought of all was the current belief that the *Encyclopædia* was the work of an organized band of conspirators against society, and that a pestilent doctrine was now made truly formidable by the confederation of its preachers into an open league. When the seventh volume appeared, it contained an article on

"Geneva," written by D'Alembert. The writer contrived a panegyric on the pastors of Geneva, of which every word was a stinging reproach to the abbés and prelates of Versailles. At the same moment Helvétius's book, *L'Esprit*, appeared, and gave a still more profound, and, let us add, a more reasonable shock to the ecclesiastical party. Authority could brook no more, and in 1759 the *Encyclopædia* was formally suppressed.

The decree, however, did not arrest the continuance of the work. The connivance of the authorities at the breach of their own official orders was common in those times of distracted government. The work went on, but with its difficulties increased by the necessity of being clandestine. And a worse thing than troublesome interference by the police now befell Diderot. D'Alembert, wearied of shifts and indignities, withdrew from the enterprise. Other powerful colleagues, Turgot among them, declined to contribute further to a book which had acquired an evil fame. Diderot was left to bring the task to an end as he best could. For seven years he laboured like a slave at the oar. He wrote several hundred articles, some of them very slight, but many of them most laborious, comprehensive, and ample. He wore out his eyesight in correcting proofs, and he wearied his soul in bringing the manuscript of less competent contributors into decent shape. He spent his days in the workshops, mastering the processes of manufactures, and his nights in reproducing on paper what he had learnt during the day. And he was incessantly harassed all the time by alarms of a descent from the police. At the last moment, when his immense work was just drawing to an end, he encountered one last and crowning mortification: he discovered that the bookseller, fearing the displeasure of the Government, had struck out from the proof sheets, after they had left Diderot's hands, all passages that he chose to think too hardy. The monument to which Diderot had given the labour of twenty long and oppressive years was irreparably mutilated and defaced. It is calculated that the average annual salary received by Diderot for his share in the *Encyclopædia* was about £120 sterling. "And then to think," said Voltaire, "that an army contractor makes £800 in a day!"

Although the *Encyclopædia* was Diderot's monumental work, he is the author of a shower of dispersed pieces that sowed nearly every field of intellectual interest with new and fruitful ideas. We find no masterpiece, but only thoughts for masterpieces; no creation, but a criticism with the quality to inspire and direct creation. He wrote plays—*le Fils Naturel* and *le Père de Famille*—and they are very insipid performances in the sentimental vein. But he accompanied them by essays on dramatic poetry, including especially the *Paradoxe sur le Comédien*, in which he announced the principles of a new drama,—the serious, domestic, bourgeois drama of real life, in opposition to the stilted conventions of the classic French stage. It was Diderot's lessons and example that gave a decisive bias to the dramatic taste of Lessing, whose plays, and his *Hamburgische Dramaturgie* (1768), mark so important an epoch in the history of the modern theatre. In the pictorial art, Diderot's criticisms are no less rich, fertile, and wide in their ideas. His article on "Beauty" in the *Encyclopædia* shows that he had mastered and passed beyond the metaphysical theories on the subject, and the *Essay on Painting* was justly described by Goethe, who thought it worth translating, as "a magnificent work, which speaks even more helpfully to the poet than to the painter, though to the painter too it is as a blazing torch." Diderot's most intimate friend was Grimm, one of the conspicuous figures of the philosophic body. Grimm wrote news-letters to various high personages in Germany, reporting what was going on in the world of art and

literature in Paris, then without a rival as the capital of the intellectual activity of Europe. Diderot helped his friend at one time and another between 1759 and 1779, by writing for him an account of the annual exhibitions of paintings. These *Salons* are among the most readable of all pieces of art criticism. They have a freshness, a reality, a life, which took their readers into a different world from the dry and concealed pedantries of the ordinary virtuoso. As has been said by Ste-Beuve, they initiated the French into a new sentiment, and introduced people to the mystery and purport of colour by ideas. "Before Diderot," Madame Necker said, "I had never seen anything in pictures except dull and lifeless colours; it was his imagination that gave them relief and life, and it is almost a new sense for which I am indebted to his genius."

Greuze was Diderot's favourite among contemporary artists, and it is easy to see why. Greuze's most characteristic pictures were the rendering in colour of the same sentiment of domestic virtue and the pathos of common life, which Diderot attempted with inferior success to represent upon the stage. For Diderot was above all things interested in the life of men,—not the abstract life of the race, but the incidents of individual character, the fortunes of a particular family, the relations of real and concrete motives in this or that special case. He delighted with the enthusiasm of a born casuist in curious puzzles of right and wrong, and in devising a conflict between the generalities of ethics and the conditions of an ingeniously contrived practical dilemma. Mostly his interest expressed itself in didactic and sympathetic form; in two, however, of the most remarkable of all his pieces, it is not sympathetic but ironical. *Jacques le Fataliste* (written in 1773, but not published until 1796) is in manner an imitation of *Tristram Shandy* and *The Sentimental Journey*. Few modern readers will find in it any true diversion. In spite of some excellent criticisms dispersed here and there, and in spite of one or two stories that are not without a certain effective realism, it must as a whole be pronounced savourless, forced, and as leaving unmoved those springs of laughter and of tears which are the common fountain of humour. *Rameau's Nephew* is a far superior performance. If there were any inevitable compulsion to name a masterpiece for Diderot, one must select this singular "farce-tragedy." Its intention has been matter of dispute; whether it was designed to be merely a satire on contemporary manners, or a reduction of the theory of self-interest to an absurdity, or the application of an ironical clench to the ethics of ordinary convention, or a mere setting for a discussion about music, or a vigorous dramatic sketch of a parasite and a human original. There is no dispute as to its curious literary flavour, its mixed qualities of pugnacity, bitterness, pity, and, in places, unflinching shamelessness. Goethe's translation (1805) was the first introduction of *Rameau's Nephew* to the European public. After executing it, he gave back the original French manuscript to Schiller, from whom he had it. No authentic French copy of it appeared until the writer had been nearly forty years in his grave (1823).

It would take several pages of this encyclopædia merely to contain the list of Diderot's miscellaneous pieces, from an infinitely graceful trifle like the *Regrets on My Old Dressing Gown* up to *D'Alembert's Dream*, where he plunges into the depths of the controversy as to the ultimate constitution of matter and the meaning of life. It is a mistake to set down Diderot for a coherent and systematic materialist. We ought to look upon him "as a philosopher in whom all the contradictions of the time struggle with one another" (Rosenkranz). That is to say, he is critical and not dogmatic. There is no unity in Diderot, as there was in Voltaire or in Rousseau. Just as in cases of conduct he loves to make new ethical assumptions and argue them

out as a professional sophist might have done, so in the speculative problems as to the organization of matter, the origin of life, the compatibility between physiological machinery and free will, he takes a certain stand-point, and follows it out more or less digressively to its consequences. He seizes an hypothesis and works it to its end, and this made him the inspirer in others of materialist doctrines which they held more definitely than he did. Just as Diderot could not attain to the concentration, the positiveness, the finality of aim needed for a master-piece of literature, so he could not attain to those qualities in the way of dogma and system. Yet he drew at last to the conclusions of materialism, and contributed many of its most declamatory pages to the *Système de la Nature* of his friend D'Holbach,—the very Bible of atheism, as some one styled it. All that he saw, if we reduce his opinions to formulas, was motion in space: "attraction and repulsion, the only truth." If matter produces life by spontaneous generation, and if man has no alternative but to obey the compulsion of nature, what remains for God to do?

In proportion as these conclusions deepened in him, the more did Diderot turn for the hope of the race to virtue; in other words, to such a regulation of conduct and motive as shall make us tender, pitiful, simple, contented. Hence his one great literary passion, his enthusiasm for Richardson, our English novelist. Hence, also, his deepening aversion for the political system of France, which made the realization of a natural and contented domestic life so hard. Diderot had almost as much to say against society as even Rousseau himself. The difference between them was that Rousseau was a fervent theist. The atheism of the Holbachians, as he called Diderot's group, was intolerable to him; and this feeling, aided by certain private perversities of humour, led to a breach of what had once been an intimate friendship between Rousseau and Diderot (1757). Diderot was still alive when the *Confessions* appeared, and he was so exasperated by Rousseau's stories about Grimm, then and always Diderot's intimate, that in 1782 he transformed a life of Seneca, that he had written four years earlier, into an *Essay on the Reigns of Claudius and Nero*, which is much less an account of Seneca than a vindication of Diderot and Grimm, and is one of the most rambling and inept productions in literature. As for the merits of the old quarrel between Rousseau and Diderot, we may agree with the latter, that too many sensible people would be in the wrong if Jean Jacques was in the right.

Varied and incessant as was Diderot's mental activity, it was not of a kind to bring him riches. He secured none of the posts that were occasionally given to needy men of letters; he could not even obtain that bare official recognition of merit which was implied by being chosen a member of the Academy. The time came for him to provide a dowry for his daughter, and he saw no other alternative than to sell his library. When the empress Catherine of Russia heard of his straits, she commissioned an agent in Paris to buy the library at a price equal to about £1000 of our money, and then she handsomely requested the philosopher to retain the books in Paris until she required them, and to constitute himself her librarian, with a yearly salary. In 1773 Diderot started on an expedition to thank his imperial benefactress in person, and he passed some months at St Petersburg. The empress received him cordially. The strange pair passed their afternoons in disputes on a thousand points of high philosophy, and they debated with a vivacity and freedom not usual in courts. "Fi, donc," said Catherine one day, when Diderot hinted that he argued with her at a disadvantage, "is there any difference among men?" Diderot returned home in 1774. Ten years remained to him, and he spent them in the industrious acquisition of new knowledge, in the composition

of a host of fragmentary pieces, some of them mentioned above, and in luminous declamations with his friends. All accounts agree that Diderot was seen at his best in conversation. "He who only knows Diderot in his writings," says Marmontel, "does not know him at all. When he grew animated in talk, and allowed his thoughts to flow in all their abundance, then he became truly ravishing. In his writings he had not the art of ensemble; the first operation which orders and places everything was too slow and too painful to him." Diderot himself was conscious of the want of literary merit in his pieces. In truth he set no high value on what he had done. It is doubtful whether he was ever alive to the waste that circumstance and temperament together made of an intelligence from which, if it had been free to work systematically, the world of thought had so much to hope. He was one of those simple, disinterested, and intellectually sterling workers to whom their own personality is as nothing in presence of the vast subjects that engage the thoughts of their lives. He wrote what he found to write, and left the piece, as Carlyle has said, "on the waste of accident, with an ostrich-like indifference." When he heard one day that a collected edition of his works was in the press at Amsterdam, he greeted the news with "peals of laughter," so well did he know the haste and the little heed with which those works had been dashed off.

Diderot died in the month of July 1784, six years after Voltaire and Rousseau, one year after his old colleague D'Alembert, and five years before D'Holbach, his host and intimate for a lifetime. Notwithstanding Diderot's peals of laughter at the thought, there is now just completed—nearly a hundred years since his death—an elaborate and exhaustive collection of his writings in twenty stout volumes, edited by MM. Assézat and Tournoux. (J. M.)

DIDO, or ELISA, the reputed founder of Carthage, was the daughter of Mtgo, Belus, or Agenor, king of Tyre. She may have been an historical character, but the stories told of her by Justin and Virgil differ essentially. She was worshipped at Carthage, and as a deity may be identified with *Juno Cælestis*, the Roman form of the Phœnician Astarte.

DIDOT, the name of a family of learned French printers and publishers.

FRANÇOIS DIDOT (1689–1757), founder of the family, was born at Paris. He began business as a bookseller and printer in 1713, and among his undertakings was a collection of the travels of his friend the Abbé Prévost, in 20 volumes (1747). It was remarkable for its typographical perfection, and was adorned with many engravings and maps.

FRANÇOIS AMBROISE DIDOT (1730–1804), son of François, made important improvements in type-founding, and was the first to attempt printing on vellum paper. Among the works which he published was the famous collection of French classics prepared by order of Louis XVI for the education of the Dauphin, and the folio edition of *L'Art de vérifier les dates*.

PIERRE FRANÇOIS DIDOT (1732–1795), brother of the preceding, devoted much attention to the art of type-founding and to paper-making. Among the works which issued from his press was an edition in folio of the *Imitatio Christi* (1788).

HENRI DIDOT (1765–1852), son of Pierre François, is celebrated for his "microscopic" editions of various standard works, for which he engraved the type when nearly seventy years of age. He was also the engraver of the *assignats* issued by the Constituent and Legislative assemblies and the Convention.

DIDOT SAINT-LÉGER, second son of Pierre François, was the inventor of the paper-making machine known in England as the Didot machine.

PIERRE DIDOT (1760–1853), eldest son of François Ambroise, is celebrated as the publisher of the beautiful "Lyonne" editions of Virgil, Horace, and Racine. The Racine, in 3 volumes folio, was pronounced in 1801 to be "the most perfect typographical production of all ages."

FIRMIN DIDOT (1764–1836), second son of François Ambroise, sustained the reputation of the family both as printer and type-founder. He invented or revived the process of stereotyping, coined its name, and first made use of the process in his edition of Callet's *Tables of Logarithms* (1795), in which he secured an accuracy till then unattainable. He published stereotyped editions of French, English, and Italian classics at a very low price. He was the author of two tragedies—*La Reine de Portugal* and *La Mort d'Annibal*; and he wrote metrical translations from Virgil, Tyrtæus, and Theocritus.

AMBROISE FIRMIN DIDOT (1790–1876), was the eldest son of the preceding. After receiving a classical education, he spent three years in Greece and in the East; and on the retirement of his father in 1827 he undertook, in conjunction with his brother Hyacinthe, the direction of the publishing business. Their greatest undertaking was a new edition of the *Theaurus Græcæ Linguae* of Henry Stephens, under the editorial care of the brothers Dindorf and M. Hase (9 vols. 1855–59). Among the numerous important works published by the brothers, the 200 volumes forming the *Bibliothèque des auteurs grecs*, *Bibliothèque latine*, and *Bibliothèque française* deserve special mention. Ambroise Firmin Didot was the first to propose (1823) a subscription in favour of the Greeks, then in insurrection against Turkish tyranny. Besides a translation of Thucydides (1833), he wrote the articles "Estienne" in the *Nouvelle Biographie Générale*, and "Typographie" in the *Encyclopédie*, as well as *Observations sur l'orthographe française* (1867), &c. In 1875 he published a very learned and elaborate monograph on Aldus Manutius. His collection of MSS, the richest in France, was said to be worth, at the time of his death, not less than 2,000,000 francs.

DIDRON, ADOLPHE NAROLÉON (1806–1867), French archæologist, was born at Hautvillers, in the department of Marne, March 13, 1806. At first a student of law, he began in 1830, by the advice of Victor Hugo, to apply himself to the study of the Christian archæology of the Middle Ages. After visiting and examining the principal churches, first of Normandy, then of Central and Southern France, he was on his return appointed by M. Guizot secretary to the Historical Committee of Arts and Monuments (1835); and in the following years he delivered several courses of lectures on Christian iconography at the Bibliothèque Royale. In 1839 he visited Greece for the purpose of examining the art of the Eastern Church, both in its buildings and its manuscripts. In 1844 he originated the *Annales Archéologiques*, a periodical devoted to his favourite subject, which he edited until his death. In 1845 he established at Paris a special archæological library, and at the same time a manufactory of painted glass. In the same year he was admitted to the Legion of Honour. His most important work is the *Iconographie Chrétienne*, of which, however, the first portion only, *Histoire de Dieu* (1843), was published. It was translated into English by E. J. Millington. Among his other works may be mentioned the *Manuel d'Iconographie Chrétienne grecque et latine* (1845), the *Iconographie des chapiteaux du palais ducal de Venise* (1857), and the *Manuel des objets de bronze et d'orfèvrerie* (1859). He died November 13, 1867.

DIDYMUS of Alexandria, an ecclesiastical writer, born in 309 or 314. Although he became blind at the age of four, before he had learned to read, he succeeded in mastering the whole circle of the sciences then known; and on enter-

ing the service of the church he was placed at the head of the Alexandrian theological school. He died in 394 or 399. Most of his theological works are lost. We possess, however, a Latin translation by Jerome, who was one of his pupils, of his Treatise on the Holy Ghost (*Liber de Spiritu Sancto*), and a similar translation by Epiphanius of his Brief Comments on the Canonical Epistles (*Breves Enarrationes in Epistolas Canonicas*). A Treatise against the Manichæans (*Liber adversus Manichæos*) is extant in the original Greek, and was first published at Bologna in 1769.

DIE (*Dea Vocontiorum*), the capital of an arrondissement in the department of Drôme, in France, is situated on the right bank of the Drôme, at the foot of Mont Glandaz, in a wide and fertile plain. The manufactures are woollen cloth, paper, leather, and silk; there is some trade in mules, cattle, and wood, and the neighbourhood produces excellent fruit, and the white wine called "Clairette de Die." The town was formerly the seat of a bishop, and, previous to the revocation of the Edict of Nantes in 1685, of a Calvinistic university. The most interesting structures of Die are the old cathedral, with granite columns from an ancient temple of Cybele, and a porch of the 11th century, the episcopal palace, the walls, flanked by towers, and the ruins of a castle—all of considerable age, the triumphal arch on the road towards Gap, known as the Porte St Marcel, portions of an aqueduct, and other Roman remains. In the vicinity are several mineral springs. The population in 1872 was 3876.

DIE SINKING. The preparation of dies for stamping coins and medals is a work requiring considerable skill and care. The steel selected should be of moderately fine grain and uniform texture, and, when polished, should show no spots or patches under a magnifying glass. Two short lengths having been cut from bars of this, and forged into rough dies, are next made as soft as possible by careful annealing,—being put in an iron pot of animal charcoal, heated to a cherry red, and allowed to cool gradually. After being faced up flatly and smoothly in a lathe, they pass into the hands of the engraver, who traces upon them their appropriate images, obverse and reverse, and works these out, with steel tools, in intaglio (The inscription is generally stamped with punches and hammer). The new *matrices*, or maternal dies, when, after repeated impressions on clay, &c., and alteration, they are found correct, are ready for hardening—a process simple enough as regards plain steel, but here very critical, seeing that a delicate engraving has to be kept intact. Each matrix is first protected with a mask, composed of fixed oil thickened with animal charcoal, or of lampblack and linseed oil. They are then placed face downwards in a crucible, and burned in animal charcoal. After being heated to a cherry red, they are taken out with a pair of tongs, plunged in a large body of water, moved about rapidly till all noise ceases, and left in the water till quite cool. If the matrix pipes or sings, there is probably a crack in it. The hardened die is next polished and tempered,—the former by holding it against a running iron disc coated with flour-emery and oil; the latter by putting it in water, which is gradually raised to the boiling point, then allowing it to cool slowly, or by placing it on a heated bar of iron till it acquires a rich straw colour. To increase its strength an iron ring may be shrunk upon it like a mechanical jacket. The matrix, treated as here described, might now be used to multiply coins or medals, but it is preferred to use it for first producing *punches*, or steel impressions in relief. With this view a steel block is procured, softened by annealing, and turned in the lathe, being made flat at the bottom and obtusely conical at the top. The block is put in the bed of a die-stamping press, and the matrix brought

down on it with force by means of the central screw. Thus a copy is produced in relief on the conical surface. Further strokes may be required to perfect it, and the punch is therefore first re-annealed (its surface having been hardened by compression), then replaced in the press, the matrix, detached from the screw, is fitted on to it, and pressed in contact by the descent of a block of steel attached to the screw. Thus, after repeated blows and frequent annealing, the impression is completed, and after being retouched by the engraver is hardened and tempered like the matrix. The matrix is now laid aside, and the punch used to produce any number of steel dies by an operation substantially similar to that by which the punch itself was obtained. These are, of course, *fac similes* of the matrix, and when completed are used for purposes of coinage. Besides coming and medalling, dies are required for a variety of purposes, such as the manufacture of buttons, steel seals, screws, and ornamental articles of metal, calico printing, &c.

DIEBITSCH-SABALKANSKI, HANS KARL FRIEDRICH ANTON (1785–1831), Count von Diebitsch and Narden, Russian field-marshal, was born in Silesia, May 13, 1785. He entered the Prussian army at the age of twelve; but four years later, by the desire of his father, a Prussian officer who had passed into the service of Russia, he also did the same. He served in the campaign of 1805, and was wounded at Austerlitz, fought at Eylau and Friedland, and after Friedland was promoted captain. During the next five years of peace he devoted himself to the study of military science, engaging once more in active service in the campaign of 1812. He distinguished himself by the recapture of Polozk; and by his defence of an important post he saved Wittgenstein's corps in retreat. He was now raised to the rank of major-general. In conjunction with General Yorck he took possession of Berlin. After the battle of Lutzen he was sent into Silesia and took part in negotiating the secret treaty of Reichenbach. Having distinguished himself at the battles of Dresden and Leipzig, he was promoted lieutenant-general. In 1814 Diebitsch strongly urged the march of the allies on Paris; and after their entry the emperor Alexander conferred on him the order of St Alexander Newski. In 1815 he married, attended the Congress of Vienna, and was afterwards made adjutant-general to the emperor. As chief of the imperial staff he accompanied the emperor to Taganrog, and was present at his death. He obtained the confidence of the emperor Nicholas, and was created baron and afterwards count. In the Turkish war of 1828–1829 Diebitsch had the chief command; he took Varna, crossed the Balkan, and concluded peace at Adrianople. His passage of the Balkan is commemorated by his surname Sabalkanski; it procured him the rank of field-marshal. On the outbreak of the insurrection in Poland, in 1830, he was appointed to the chief command. His good genius, however, now failed him. After the battle of Ostrolenka he transferred his head quarters to Kleckzewo, near Pultusk, where he died of cholera, June 10, 1831.

DIEPENBECK, ABRAHAM VAN (1599–1675), was born at Herzogenbusch, and studied painting at Antwerp, where he became one of Rubens's "hundred pupils." Rubens complains in his letters that, being overwhelmed with applications for apprentices' indentures, he refused to accept as disciples even the children of some of his best friends. Diepenbeck was one of those who was fortunate enough to obtain admission to Rubens's workshop. But he was not one of the cleverest of Rubens's followers, and he succeeded, at the best, in imitating the style and aping the peculiarities of his master. We see this in his earliest pictures—a portrait dated 1629 in the Munich Pinakothek, and a Distribution of Alms of the same period in the same

collection. Yet even at this time there were moments when Diepenbeck probably fancied that he might take another path. A solitary copperplate executed with his own hand in 1630 represents a peasant sitting under a tree holding the bridle of an ass, and this is a minute and finished specimen of the engraver's art which shows that the master might at one time have hoped to rival the animal draughtsmen who flourished in the schools of Holland. However, large commissions now poured in upon him; he was asked for altar-pieces, subject-pieces, and pagan allegories. He was tempted to try the profession of a glass-painter, and at last he gave up every other occupation for the lucrative business of a draughtsman and designer for engravings. Most of Diepenbeck's important canvases are in Continental galleries. The best are the Marriage of St Catherine at Berlin, and Mary with Angels Wailing over the Dead Body of Christ in the Belvedere at Vienna, the first a very fair specimen of the artist's skill, the second a picture of more energy and feeling than might be expected from one who knew more of the outer form than of the spirit of Rubens. Then we have a fine Entombment at Brunswick, and St Francis Adoring the Sacrament at the museum of Brussels, Clelia and her Nymphs Flying from the Presence and Pursuit of Porcenna in two examples at Berlin and Paris, and Neptune and Amphitrite at Dresden. In all these compositions the drawing and execution are after the fashion of Rubens, though inferior to Rubens in harmony of tone and force of contrasted light and shade. Occasionally a tendency may be observed to imitate the style of Vandyck, for whom, in respect of pictures, Diepenbeck in his lifetime was frequently taken. But Diepenbeck spent much less of his leisure on canvases than on glass-painting. Though he failed to master the secrets of gorgeous tinting, which were lost, apparently for ever in the 16th century, he was constantly employed during the best years of his life in that branch of his profession. In 1635 he finished forty scenes from the life of St Francis of Paula in the church of the Minimes at Antwerp. In 1644 he received payment for four windows in St Jacques of Antwerp, two of which are still preserved, and represent the Virgins to whom Christ appears after the Resurrection. The windows ascribed to him at St Gudule of Brussels are now proved to have been executed from the cartoons of Theodore van Thulden. On the occasion of his matriculation at Antwerp in 1638-9, Diepenbeck was registered in the guild of St Luke as a glass-painter. He resigned his membership in the Artist Club of the Violette in 1542, apparently because he felt hurt by a valuation then made of drawings furnished for copper-plates to the engraver Pieter de Jode. The earliest record of his residence at Antwerp is that of his election to the brotherhood (*Sodaliteit*) "of the Bachelors" in 1634. It is probable that before this time he had visited Rome and London, as noted in the work of Honbraken. In 1636 he was made a burghess of Antwerp. He married twice, in 1637 and 1652. His death took place in December 1675, and his funeral was celebrated at St Jacques of Antwerp on the 31st day of that month.

Consult, besides earlier authorities, the Antwerp *Laggenen*

DIEPPE, a seaport town of France, at the head of an arrondissement in the department of Seine-Inférieure, 38 miles north of Rouen and 125 north-west of Paris by rail, in 49° 55' 35" N lat and 1° 5' 9" E. long. It lies at the mouth of the River Arques, in a hollow of the coast,—the main part of the town being on the west side of the river, and the suburb of Pollet on the east. Its principal street stretches for about a mile along the shore, and terminates in the west at the foot of the chalk cliff, which is surmounted by a castle of the 15th century, now employed as barracks.

The whole town has a modern aspect; its streets are wide and regular, and its houses mostly built of brick. The principal building is the church of St Jacques, which was

founded in the 13th century, but consists in good measure of considerably later workmanship, and has in some portions been restored in the present century; the main entrance (of the 14th century) and the Anglo chapel are worthy of special remark. It is sufficient to mention the church of St Remi (1522-1640), the town-house, the hospital, the theatre, and the communal college which preserves some fragments of Anglo's mansion. As the chief town of an arrondissement, and an important seaport, Dieppe is the seat of a large number of public offices. Its harbour, which has been greatly improved during the present century, is protected by two piers, admits vessels of 500 tons burden, and has a large floating dock. There is regular steamboat communication with England, the passage to Newhaven being accomplished in about six hours. The general trade of the town, both export and import, is extensive; and it carries on ship-building, rope-spinning, cooperage, watchmaking, and a remarkable manufacture of articles in ivory and bone, which dates from the 15th century. The tobacco factories alone employ upwards of 1000 work people. Oysters in large numbers are fattened in the *retenue des chasses*; and the fishermen of Pollet are among the main providers of the Parisian markets. Ever since the time of the duchess of Berry (whose favourite residence, the *maison Quenouille*, is still pointed out) the town has been a fashionable watering-place; and in 1857 a large bathing establishment was erected after the model of the Crystal Palace. The so-called Jardin Anglais, the Cours Bourbon, and the cliffs are the principal promenades; and the castle of Arques, the Manoir d'Ango, the abbey of St Victor, and the ancient camp, locally known as *la cité des Limes*, are the most interesting objects of interest in the neighbourhood. Population in 1851, 16,216; and in 1872, 19,757.

It may be safely asserted, on the authority of its name, that Dieppe owed its origin to a band of Norman adventurers, who found its "diep" or inlet suitable for their ships. Its first castle was probably built in 1188 by Henry II. of England, and it was counted a place of some importance when Philip Augustus attacked it in 1195. By Richard I. of England it was bestowed, in 1197, on the archbishop of Rouen in return for certain territory in the neighbourhood of the episcopal city. In 1339 it was plundered by the English, but it soon recovered from the blow, and in spite of the opposition of the Lords of Hantot, managed to surround itself with fortifications. Its commercial activity was already great, and it is believed its seamen visited the coast of Guinea in 1339, and founded there a Petit Dieppe in 1365. A siege undertaken in 1442 by Talbot in person was raised by the Dauphin, afterwards Louis XI., and the day of the deliverance continued for centuries to be celebrated by a great procession and miracle plays. In the beginning of the 16th century we find Parmentier, a native of the

town, taking vessels to Brazil and Sumatra; and a little later, its merchant prince, Anglo, was able to blockade the Portuguese fleet in the Tagus. Its inhabitants in great numbers embraced the Reformed religion; and they were among the first to acknowledge Henry IV., who fought one of his great battles at the neighbouring village of Arques. Few of the cities of France suffered more from the revocation of the Edict of Nantes in 1685, and this blow was followed in 1694 by a terrible bombardment on the part of the English and Dutch. The town was rebuilt after the peace of Ryswick, but the decrease of its population and the deterioration of its port prevented the restoration of its commercial prosperity. Within the present century, however, especially since communication by rail was effected with Paris, it has made rapid advances. During the Franco-German war the town was occupied by the Germans from December 1870 till July 1871.

DIES, CHRISTOPH ALBERT (1755-1822), was born at Hanover, and learned the rudiments of art in his native place. For one year he studied in the academy of Dusseldorf, and then he started at the age of twenty with thirty ducats in his pocket for Rome. There he established his domicile, and lived a frugal life till 1796. Copying pictures, chiefly by Salvator Rosa, for a livelihood, his taste led him to draw and paint from nature in Tivoli, Albano, and other picturesque places in the vicinity of Rome. Naples, the birthplace of his favourite master, he visited more than once for the same reasons. In this way he became a bold executant in water colours and in oil, though he failed to acquire any originality of his own. Lord Bristol, who encouraged him as a copyist, predicted that he would be a second Salvator Rosa. But Dies was not of the wood which makes original artists. Besides other disqualifications, he had necessities which forced him to give up the great career of an independent painter. David, then composing his *Horatii* at Rome, wished to take him to Paris. But Dies had reasons for not accepting the offer. He was courting a young Roman whom he subsequently married. Meanwhile he had made the acquaintance of Volpato, for whom he executed numerous drawings, and this no doubt suggested the plan, which he afterwards carried out, of publishing, in partnership with Méchan, Reinhardt, and Frauenholz, the series of plates known as the *Collection de vues pittoresques de l'Italie*, published in 72 sheets at Nuremberg in 1799. With so many irons in the fire Dies naturally lost the power of concentration. Other causes combined to affect his talent. In 1787 he swallowed by mistake three-quarters of an ounce of sugar of lead. His recovery from this poison was slow and incomplete. His return to Germany was hastened by it. He had hoped that the air of his native country would improve his health. He settled at Vienna, and lived there in the old way on the produce of his brush as a landscape painter, and on that of his pencil or graver as a draughtsman and etcher. But instead of getting better as he had hoped, his condition became worse, and he even lost the use of one of his hands. In this condition he turned from painting to music, and spent his leisure hours in the pleasures of authorship. He did not long survive, dying at Vienna in 1822, after long years of chronic suffering. From two pictures now in the Belvedere gallery, and from numerous engraved drawings from the neighbourhood of Tivoli, we gather that Dies was never destined to rise above a respectable mediocrity. He followed Salvator Rosa's example in imitating the manner of Claude Lorraine. But Salvator adapted the style of Claude, whilst Dies did no more than copy it.

DIEST, a town and fortress of Belgium, in the province of Brabant, and the arrondissement of Löwen, is situated

on the Demer, 28 miles E. by N. of Brussels. The manufactured are hats, leather, stockings, beer, and spirits. It was taken from the French by Marlborough in 1705, and recaptured the same year. The fortifications, which replace the old ramparts and walls, were commenced in 1837, and finished in 1853. The population in 1866 was 7561.

DIET (German, *Reichstag*). The origin of the German Diet is to be sought in the national assembly, which was a common institution of the Teutonic race. From the earliest recorded times we find all leading questions first discussed by the chiefs and then referred to the assembly of the clan or tribe, in which every freeman had a voice.

The earliest Diets of the German or Holy Roman Empire were assemblies in which the monarch deliberated with his subjects on the common interests of the empire. Originally all members were bound by their feudal tenure to be present, and if absent they not only forfeited their vote but were liable to fine. Thus the Diet was a feudal, not a representative, Parliament. As by degrees the feudatories of the emperor turned into independent sovereigns, the Diet became nothing more than a congress of princes. The emperor, instead of presiding in person, was represented by a delegate called principal commissarius, and the princes sent envoys, the right of suffrage being no longer personal, but attached to certain territories or districts.

At first the emperor was, in theory at least, elected by universal suffrage; a candidate was chosen by the chief men, and their nominee approved by the people. Thus we read that at the election of Conrad II. 50,000, and at that of Lothaire II. 60,000 persons were present. In time this custom of nominating the emperor grew into an established right, which, under the name of *prætaxation*, was arrogated by the chief princes of the empire. Thus the chief function of the Diet, the choice of an emperor, became the prerogative of a few of its most powerful members, who claimed the right not only of election but of deposition. Thus in 1298 Adolphus of Nassau was deposed, and Albert of Austria chosen in his stead. The right of the electors and the forms and rules of election were defined and settled by the famous instrument of Charles IV. known as the Golden Bull, 1356.

The Diet consisted of three bodies, who met and voted in separate colleges,—(1) the electoral college, (2) the princes of the empire spiritual and temporal, (3) the free imperial cities.

1. In a law of Otho IV. (1208), we find the right of electing an emperor vested in the electoral college of seven. These consisted of three spiritual princes—the archbishops of Mentz, Treves, and Cologne,—and four secular electors—the duke of Saxony, the count palatine of the Rhine, the king of Bohemia, and the margrave of Brandenburg. The former sat as recognized heads of the German church. The latter would naturally have been the dukes of Saxony, Franconia, Swabia, and Bavaria; but when Bavaria was united with the county palatine its right was transferred to Bohemia; that of Swabia was, on the accession of Frederick (who by his election was incapacitated from voting), delegated to Brandenburg, and by it retained; and probably that of Franconia was for similar reason forfeited (see Dunham, *Germanic Empire*, i 216).

2. The princes of the empire had in all other respects, save that of electing an emperor, the same rights as the dukes or electors. They consisted of the archbishop of Salzburg, 20 bishops, 4 abbots, and 2 prebendaries, and of 44 temporal princes, though this number was afterwards largely augmented. Of these several, such as the archduke of Austria, and the dukes of Brunswick and Burgundy, were in rank and power more than equals of the electors.

3. The free imperial cities formed a college divided into two benches,—the Swabian, with 37 cities, and the Rhenish, with 14. They first appear at the Diet under Henry VII., but their position was not recognized till the peace of Westphalia. The power exercised by this municipal constituent of the Diet was small and strictly limited. Only what had been agreed upon by the electors and princes could be submitted to the college of cities for their sanction. The lower nobility, the knights of the empire, and the commons were unrepresented.

Each college voted separately; when the three colleges agreed, the decree or *recess* of the Diet, as it was called, was submitted to the emperor for his ratification; but the emperor had no power to modify it, and no resolution which affected the general interests of the empire could be passed without the approbation of the Diet.

Besides extraordinary meetings, the Diet was regularly convened twice a year. At the spring session the general business of the empire was discussed, laws were passed, alliances concluded, rebels proscribed, and grants of fiefs confirmed. The autumn session was occupied with finances and attended only by dukes, counts, and officers of administration. From 1663 the Diet met at Regensburg.

From the end of the Thirty Years' War the power of the Diet steadily declined. The Peace of Westphalia, while confirming the rights of the Diet as against the emperor, at the same time, by recognizing the territorial independence of the German princes, so limited the province of the federative assembly that, to quote the words of Frederick the Great, the Diet became "a mere shadow, a congress of publicists more busied with forms than things, like dogs who bay the moon."

The most important Diets were the following:—

- 1106 Mainz. Henry IV. deposed on motion of his son
- 1142. Frankfort. Conrad surrendered Saxony to Henry the Lion.
- 1356 Nuremberg. The Golden Bull.
- 1486. Worms. Private defiance forbidden, and Imperial Chamber established.
- 1521. Worms. Edict against Luther.
- 1526 Spire. Choice of religion allowed to the several states.
- 1529 Spire. Edict of Worms re-enacted.
- 1580 Augsburg. The confession of Augsburg presented.
- 1806 Regensburg. Napoleon's envoy announces the dissolution of the empire. Francis II resigns imperial crown.
- 1848. Frankfort. First Diet of Germanic confederation.

DIETETICS. The application of science to the regulation of the continuous demands of the body for nutriment aims mainly at three objects—Health, Pleasure, and Economy. They are rarely inconsistent with one another, but yet require separate consideration, as under varying circumstances each may claim the most prominent place in our thoughts.

Influence of Diet upon Health.

The influence of diet upon the health of a man begins at the earliest stage of his life, and indeed is then greater than at any other period. It is varied by the several phases of internal growth and of external relations, and in old age is still important in prolonging existence, and rendering it agreeable and useful.

Diet in Infancy.—No food has as yet been found so suitable for the young of all animals as their mother's milk. And this has not been from want of seeking. Dr Brouzet (*Sur l'Éducation médicale des Enfants*, i. p. 165) has such a bad opinion of human mothers, that he expresses a wish for the state to interfere and prevent them from suckling their children, lest they should communicate immorality and disease! A still more determined pessimist was the famous chemist Van Helmont, who thought life had been reduced to its present shortness by our inborn propensities, and proposed to substitute bread boiled in beer and honey for milk, which latter he calls

"brute's food." Baron Liebig has followed the lead with a "Food for infants," in the prescription for which half ounces and quarter grains figure freely, and which has to be prepared on a slow fire, and after a few minutes boiled well. And after all not nearly such a close imitation of human milk is made as by the addition to fresh cow's milk of half its bulk of soft water, in each pint of which has been mixed a heaped up teaspoonful of powdered "sugar of milk" and a pinch of phosphate of lime. Indeed, in default of these cheap chemicals, the milk and water alone, when fresh and pure, are safer than an artificial compound which requires cooking. And experience shows that the best mode of administering food to the young is also that which is most widely adopted throughout warm-blooded nature, namely, in a fresh, tepid, liquid state, frequently, and in small quantities at a time.

Empirical observation is fully supported in these deductions by physiological and chemical science. Milk contains of—

Water	88 per cent.
Oleaginous matter (cream or butter)	3 "
Nitrogenous matter (cheese and albumen)	4 "
Hydrocarbon (sugar)	4½ "
Saline matter (phosphate of lime, chloride of sodium, iron, &c.)	½ "

These are at once the constituents and the proportions of the constituents of food suited to a weakly rapidly-growing animal. The large quantity of water makes it pass easily through the soft absorbent walls of the digestive canal, and the complete suspension in an alkaline fluid of the finely divided fat and nitrogenous matter introduce more of them than could be effected were they in a solid form. The fat is the germ of new cellular growth, and the nitrogenous matter is by the new cells formed into flesh, which is doubling its bulk mouthfuly. The phosphate of lime is required for the hardening bones, the chloride of sodium and the iron for the daily increasing amount of blood in circulation. Milk may be said to be still alive as it leaves the breast fresh and warm, and quickly becomes living blood in the infant's veins. A very slight chemical change is requisite. Its frequent administration is demanded by the rapid absorption, and the absence of regular meals prevents the overloading of the delicate young stomach with more than it can hold at once.

The wholesomest nutriment for the first six months is milk alone. A vigorous baby can indeed bear with impunity much rough usage, and often appears none the worse for a certain quantity of farinaceous food; but the majority do not get habituated to it, without an exhibition of dislike which indicates rebellion of the bowels.

To give judicious diet its fair chance the frame must be well protected from the cold; and just in proportion as the normal temperature of the body is maintained so does growth prosper, as is satisfactorily proved by experiments on the young of the lower animals.

It is only when the teeth are on their way to the front, as shown by dribbling, that the parotid glands secrete an active saliva capable of digesting bread stuffs. Till then anything but milk must be given tentatively, and considered in the light of a means of education for its future mode of nutrition. Among the varieties of such means, the most generally applicable are broth and beef tea, at first pure, and then thickened with tapioca and arrowroot. Chicken soup, made with a little cream and sugar, serves as a change. Baked flour, biscuit powder, tops and bottoms, should all have their turn; change is necessary in the imperfect dietary which art supplies, and for change the stomach should be prepared by habit.

The consequences of premature weaning are insidious. The external aspect of the child is that of health, its muscles

are strong, but the bones do not harden in proportion, and if it tries to walk its limbs give way, and it is said to be suffering from rachitis or "rickets."

These consequences follow in other animals as surely as in the human race, and in them it was possible to make the experiment crucial. A gentleman named Gnerin set himself to find if he could produce rickets at will. He took a number of puppies in equally good condition, and having let them suckle for a time, he suddenly weaned half of them and fed them on raw meat, a fare which at first thought would seem the most suitable for carnivorous animals. Nevertheless, after a short time, those which continued to take the mother's milk had grown strong and hearty, whilst those which had been treated with a more substantial dietary pined, and frequently threw up their victuals, then their limbs bent, and at the end of about four months they showed all the symptoms of confirmed rickets. From these experiments we must conclude that the rachitis depended mainly on the derangements of nutrition brought on by improper diet. A diet which is taken at a wrong season may fairly be called improper. For carnivora, it is flesh before the age of suckling has passed; for herbivora (and an experiment bearing on the point has been made on pigs), it is vegetable feeding begun when they ought to be at the teat.¹

The time for weaning should be fixed partly by the child's age, partly by the growth of the teeth. The troubles to which children are subject at this crisis are usually gastric, such as are induced by summer weather; therefore at that season the weaning should be postponed, whereas in winter it should be hurried forward. The first group of teeth nine times out of ten consists of the lower central front teeth, which may appear any time during the sixth and seventh month. The mother may then begin to diminish the number of suckling times; and by a month she can have reduced them to twice a day, so as to be ready when the second group makes its way through the upper front gums to cut off the supply altogether. The third group, the lateral incisors and first grinders, usually after the first anniversary of birth give notice that solid food can be chewed. But it is prudent to let dairy milk form a considerable portion of the fare till the eye teeth are cut, which seldom happens till the eighteenth or twentieth month. At this period children are liable to diarrhoea, convulsions, irritation of the brain, rashes, and febrile catarrhs. In such cases it is often advisable to resume a complete milk diet, and sometimes a child's life has been saved by its reapplication to the breast. These means are most feasible when the patient is accustomed to milk, indeed, if not, the latter expedient is hardly possible.

Diet in Childhood and Youth—At this stage of life the diet must obviously be the best, which is a transition from that of infancy to that of adult age. Growth is not completed, but yet entire surrender of every consideration to the claim of growth is not possible, nor indeed desirable. Moreover that abundance of adipose tissue, or reserve new growth, which a baby can bear, is an impediment to the due education of the muscles of the boy or girl. The supply of nutriment needs not to be so continuous as before, but at the same time should be more frequent than for the adult. Up to at least fourteen or fifteen years of age the rule should be four meals a day, varied indeed, but nearly equal in nutritive power and in quantity, that is to say, all moderate, all sufficient. The maturity the body then reaches involves a hardening and enlargement of the bones and cartilages, and a strengthening of the digestive organs, which in healthy young persons enables us to dispense with some of the

watchful care bestowed upon their diet. Three full meals a day are generally sufficient, and the requirements of mental training may be allowed to a certain extent to modify the attention to nutrition which has hitherto been paramount. But it must not be forgotten that the changes in figure and in internal organs are not completed till several years have passed, and that they involve increased growth and demand full supplies. As less bulky food is used, care should be taken that it is sufficiently nutritious, and habits should be acquired which conduce to making the most of it for the maintenance of strength.

The nutritiousness of food depends on *digestibility* and *concentration*. Food is digestible when it yields readily its constituents to the fluids destined for their reduction to absorbable chyme. It is more or less concentrated, according as a given weight contains more or less matter capable of supporting life. The degree in which they possess these qualifications united constitutes the absolute nutritive value of alimentary matters.

The degree of cohesion in the viands influences digestibility. Tough articles incapable of being completely ground up by the teeth, remain unsoft, while fluids and semifluids lead the van of digestibles. The tissues of young vegetables and young animals are for this reason more digestible than old specimens. It is desirable also that the *post mortem* rigidity, which lasts several days in most instances, should have merged into softness before the meat is cooked, or should have been anticipated by cooking before the flesh is cold. In warm climates and exceptionally warm weather the latter course is the preferable. The dietician, especially when the feeding of the young is in question, will prefer those methods of culinary preparation which most break up the natural cohesion of the viands. And it may be noticed that the force of cohesion acts in all directions, and that it is no advantage for an article to be laterally friable if it remains strung in a longitudinal direction.

Fat interposed between the component parts of food diminishes its digestibility. It is the interstitial fat between the fasciculi of muscular fibre in beef which renders it to young persons and to dyspeptics less digestible than mutton.

A temperature above that of the body retards digestion. Meat, which is digested by the gastric juice in the stomach, has time to cool before it gets there, but farinaceous food, which depends for its conversion into chyme on the salivary glands, suffers a serious loss if by reason of being too hot it cannot avail itself of the saliva supplied by the mouth. It should also be borne in mind that a temperature much above that of the body cracks the enamel of the teeth.

Excessive concentration impairs digestibility. The principal medium by which nutriment is carried through the absorbent membrane of the digestive canal is water. There is no doubt it passes more rapidly by endosmosis than anything else. The removal, then, of water is an injury to viands, and drying, salting, over-frying, over roasting, and even over-boiling renders them less soluble in the digestive juices, and so less nutritious. A familiar illustration of this may be taken from eggs. Let an egg be lightly boiled, poached in water, custarded, or raw, and the stomach even of an invalid can bear it, but let it be baked in a pudding which requires a hot oven, or boiled hard, or otherwise submitted to a high temperature for a prolonged period, and it becomes a tasteless, leathery substance, which can be of no more use in the stomach than so much skin or hair. It is obvious then that it is mainly in a commercial point of view that articles of diet can be called nutritious in proportion to their concentration. About this there can be no question, milk adulterated from the pump is worth so much less than pure milk, and a pound of beef steak sustains a man longer than a pint of real broth.

¹ Trousseau, *Clinique Médicale*, vol. III. p. 484, 3d edit.

The attainment of nutritiousness by concentration is of considerable importance to travellers and in military medicine. There are not a few strategists who attribute the success of the Germans in the war of 1870 to the easily carried and easily prepared food supplied to them by the sausage-makers of Berlin. Concentration of viands carried to excess, so as to be likely to affect the health, is usually made manifest by a diminution in the secretion of urine and its condensed condition, while, on the other hand, if dilution is needlessly great, the action of the kidneys is excessive. Now the urine of young persons is naturally of lower specific gravity, that is, more aqueous, than that of adults. If it is found to equal in density the excretion of full growth, or if it is observed to be voided but rarely, the meals should be made more bulky, or better still, more frequent, so as not to overload the stomach.

An over-concentrated diet often induces costiveness. This should be counteracted by green vegetables and other dilute appetizing dishes, and never by purgative drugs. The habit of taking a considerable quantity and variety of fresh green vegetables has the further advantage of preventing that tendency to minor developments of scurvy which is not uncommonly found in youths nourished mainly on animal food. A softness or friability of the gums is one of the first signs of this. If the mouth bleeds after the application of a tooth brush, the use of fresh vegetables at every meal should be enforced.

The young are peculiarly liable to be affected by poisons conveyed in fluids. Their sensitive frames absorb quickly, and quickly turn to evil account such substances, even when diluted to an extent which makes them harmless to adults. The water therefore with which families, and still more with which schools are supplied, should be carefully subjected to analysis. Wherever a trace of lead is found, means should be adopted to remove the source of it, and organic products should have their origin clearly accounted for, and all possibility of sewage contamination excluded. These precautions are essential, in spite of the grown-up portion of the household having habitually used the water without injury.

Fresh milk has long had a bad popular reputation as occasionally conveying fever, and in some parts of Ireland the peasantry can hardly ever be got to take it "raw." This is quite irrespective of the state of the cattle which furnish it, no cases of disease thus communicated have ever been traced home to sick cows. It is probably always due either to adulteration with dirty water, or to the vessels being washed in that dangerous medium, or to their being exposed to air loaded with elements of contagion.

Up to the period of full development the daily use of wine should be allowed only during illness and the express attendance of a medical adviser. Its habitual consumption by healthy children hastens forward the crisis of puberty, checks growth, and habituates them to the artificial sensation induced by alcohol.

Diet for Bodily Labour.—It seems certain that the old theory of Liebig, which attributed the whole of the force exhibited in muscular movements to the oxidation of muscular tissue, is untenable. There is not enough of the material oxidized, that is to say, destroyed, and carried away as urea and other nitrogenous excretions, to generate so much force, as measured by the method of Joule. On the other hand, Traube goes too far when he would make out that in the performance of muscular work the metamorphosis of the organized constituents of contractile tissue is not involved, and that non-nitrogenous substances alone are consumed. The prolonged feats of walking performed by the pedestrian Weston in 1876 vastly

increased the amounts excreted of those elements of the urine which are derived from the oxidation of muscle and nerve.¹ The urea formed by the destructive assimilation of contractile fibre, and the phosphates whose main source is nervous tissue, were each nearly doubled during and shortly after the extraordinary strain upon those parts of the body. As might be expected, the machinery wears away quicker when it is harder worked, and requires to be repaired immediately by an enhanced quantity of new material, or it will be worn beyond the power of repair. The daily supply, therefore, of digestible nitrogenous food, meat *par excellence*, must be increased whenever the muscular exercise is increased. In making the recent extension of railways in Sicily, the progress was retarded by the slack work done by the Sicilian navvies compared with that got through by the English gangs. The former took scarcely any meat, preferring to save the wages expended by their comrades in that way. The idea occurred to the contractor of paying the men partly in money and partly in meat, and the result was a marked increase in the amount of work executed, which was brought nearly up to the British average. A mixed diet, with an increase in the proportionate quantity of meat when extra corporeal exertion is required, is the wholesomest, as well as the most economical, for all sorts of manual labourers.

It is absolutely essential that the fleshly machinery for doing work should be continuously replaced by flesh food, as it becomes worn out. Nitrogenous aliment after a few chemical changes replaces the lost muscle which has passed away in the excretions; just as the engineer makes ore into steel and renews the corroded boiler plate or thinned piston. Now, as the renewal of the plate or piston is a "stimulus" to the augmented performances of the engine, so meat is a "stimulus" to augmented muscular action. Taken in a digestible form during exertion, it allows the exertion to be continued longer, with greater ease and less consequent exhaustion. According to the testimony of soldiers experimentally put through forced marches of twenty miles a day, with loads of half a hundredweight each, "meat-extract" bears away the palm from the other reputed stimulants commonly compared with it (*viz.*, rum and coffee). "It does not put a spirit into you for a few miles only, but has a lasting effect; if I were ordered for continuous marching, and had my choice, I would certainly take the meat extract," said an unprejudiced sergeant to Dr Parkes, who was the conductor of the experiments alluded to.²

When the continuous repair of the muscular machinery is fully secured, the production of heat and force is most readily provided for by vegetable aliment, by reason of the large proportion of carbon which it contains. In assigning their physiological functions to the several sorts of food, nearly all the business of begetting active force should apparently be ascribed to the solid hydrocarbons, starch and fat, by their conversion into carbonic acid. It is not necessary to be acquainted with every step of the process, which in the body we confessedly are not, to appreciate the argument. It is clearly important that these elements of diet should be furnished in sufficient quantity and in a digestible form. In additions to diet made in consequence of additional bodily work not only should the stimulus of animal food be attended to, but the bulk of starch and fat in the rations should be augmented even in larger

¹ See Dr Pavy on Weston's walk, in *Lancet* of Dec. 23, 1876. The urea excreted when walking bore to that excreted during rest the relation of 17 to 10, phosphoric acid 19 to 10, lime 15 to 10, &c.

² On the *Issue of a Spirit Ration during the Ashantee Campaign of 1874*, by E. A. Parkes, M.D., Professor of Military Hygiene in the Army Medical School. London, 1875.

proportion, for these aliments are the most direct contributors of force.¹

"Training" for athletic sports is based on the principles above enunciated. The usual time allotted to it is six weeks, and the objects to be attained in this period may be described as—

- (1.) The removal of superfluous fat and water;
- (2.) The increase of contractile power in the muscles;
- (3.) Increased endurance;
- (4.) "Wind," that is to say, a power of breathing and circulating the blood steadily in spite of exertion.

The first is aimed at by considerably adding to the daily amount of nitrogenous and by diminishing farinaceous and liquid food, and providing that it should be so consumed as to be fully digested. The second and third are secured by gradually increasing the demands made upon the muscles, till they have learnt to exert at will all the powers of which they are capable, and for as long a period as the natural structure of the individual frame permits. "Wind" is improved by choosing as part of the training an exercise, such as running, which can be sustained only when the respiratory and circulating organs do their duty fairly.

As an example, the Oxford system of training for the summer boat-races may be cited. It may be considered a typical regimen for fully developing a young man's corporeal powers to fulfil the demands of an extraordinary exertion, a standard which may be modified according to the circumstances for which the training is required. It is as follows:—

A Day's Training.

Rise about 7 A M		
Exercise .. .	A short walk or run.	Not compulsory
Breakfast at 8 30	Of tea, Meat, beef or mutton	As little as possible.
	Bread or dry toast .	Underdone
Exercise in forenoon	None.	Crust only recommended
	Meat, much the same as for breakfast	
Dinner at 2 P M	Bread	Crust only recommended.
	Vegetables, none ..	Not always adhered to.
	Beer, one pint	
Exercise	About 5 o'clock start for the river, and row twice over the course, the speed increasing with the strength of the crew.	
Supper at 8 30 or 9 P.M.	Meat, cold Bread, and perhaps a little jelly or water-cresses.	
Bed about 10	Beer, one pint.	

¹ This is well illustrated by a remarkable feat performed on the Great Western Railway in the summer of 1872. It was necessary to shift the rails from the broad to the narrow gauge on upwards of 500 miles of permanent way within a fortnight. The task was enormous, for the Great Western is one of the few English lines whose rails are held down by bolts screwed into nuts. All these had to be unscrewed and replaced after removing the heavy rail two feet. About 3000 men were employed, working double time, sometimes from 4 in the morning till 9 at night, and, without one being sick or drunk, they accomplished the work in the prescribed time. The scheme for generating muscular power was this. The men were huddled along the line, so as not to waste their strength by coming and going, and they brought with them bacon, bread, cheese, cocoa, &c., to provide their usual meals at usual times. But they had no beer, nor alcohol in any form. A pound and a half of oatmeal and half a pound of sugar was allowed extra to each man daily, and for every gang of 21 a cock was provided. The first thing done in the morning was to breakfast; and then the cook and his caldron started along the line till water was found convenient; a fireplace of stones was built, and the pot boiled. Oatmeal was then sprinkled into it with sugar,

The Cambridge system differs very slightly, and in neither is any exaggerated severity of discipline enforced, while some latitude is permitted to peculiarities and a wish for variety, and plenty of time is left for business and social intercourse. Other plans are objectionable, from involving, without any corresponding advantage, a complete departure from the usual habits of the educated classes. For instance, according to Clasper, dinner is to be at noon, with only a light tea afterwards, and no supper. Then a country walk of four or five miles is to be taken before breakfast, and two hours row afterwards, and another hard row between dinner and tea.³ "Stonehenge," again, requires the time between breakfast and dinner to be spent entirely on billiards, skittles, quoits, rowing, and running, in spite of another hour's row being prescribed at 6 P.M. He also requires the aspirant for athletic honours to sleep between 10 and 11 hours.⁴ Only professionals will carry out such rules, and even they do not either benefit their health or lengthen their lives by the sacrifice. For it is notorious that "over-training" leads to a condition of system in which the sufferers describe themselves as "fallen to pieces." The most peculiar symptom is a sudden loss of voluntary power after exertion. It is sometimes called "fainting," but there is no loss of sense, and it is quickly relieved by liquid food. It is to the pathologist a timely warning of that consequence of overstrained muscle which constitutes paralysis scriptorum, turner's palsy, and blacksmith's palsy, and which results in fatty degeneration of the red muscular fibre. To get and to keep its health a muscle needs a constant alternation of active contraction and rest, and an enforced protraction of either one or the other leads to the loss of vital properties. The limbs of an Indian fakir, voluntarily held in a strained posture, or those of a bed-ridden invalid, are equally apt to become useless. Overtrained persons are also liable to a languor and apparent weakness, which is found on examination to depend on an excessive secretion of urea by the kidneys.

Such are not the results, however, of the training adopted at the universities, by which it would appear that the constitution is strengthened, the intellect sharpened, and life lengthened. Dr John Morgan (*University Oars*, 1873), has collected statistics of the subsequent health of those who have rowed in the university races since 1829, and he finds that, whereas at twenty years of age, according to Farr's life tables, average expectation of survival is forty years, for these oarsmen it is forty-two years. Moreover, in the cases of death, inquiry into its causes exhibits evidence of good constitutions rather than the contrary, the causes consisting largely of fevers and accidents, to which the vigorous and active are more exposed than the sick. And

and thoroughly well boiled till thin gruel was made. As soon as the "shout for drunk" was heard, buckets were filled and carried round with small pannikins to convey the liquid to the panting mouths. The men liked it exceedingly, and learned by experience the importance of having it well cooked.

The incident may remind the reader of classical medicine of Hippocrates, who considers the culinary preparation of oatmeal pisan so important that in a short treatise *On the Treatment of Acute Disease* he devotes to it the only cookery recipe he has inserted in his works. He describes how it is to be boiled till it can swell no longer (so that it may swell no more in the stomach), how it is to be settled and strained (through a coarse cullender). He prescribes it indeed for sick people but he would have been the first to agree with our advanced physiologists in the opinion that overstrained muscular effort produces the same effects as continued fever (*ἡ υπερβολὴ καθίσταται μακρότερον*), its chief dangers lying in rise of temperature and arrested cutaneous action, and that its true antagonist is nutriment capable of rapid absorption, dissolved in that most essential nutriment, water.

² See MacLaren's *Training in Theory and Practice*, appendix to edition 1866.

⁴ Article "Boat-Racing," in *British Rural Sports*, 1861.

it is not at the expense of the mind that the body is cultivated, for this roll of athletes is adorned with the names of bishops, poets, queen's counsel, &c.

Training greatly increases the vital capacity of the chest, so that much more air can be blown in and out of the lungs, and with greater force, than previously. And this vital capacity endures longer than the other improvements. It is evidence of the permanent elasticity of the pulmonary tissue, and an efficient protection against asthma, emphysema, and other degenerations of the organ of breathing.

Indigestion, sleeplessness, nervous indecision, palpitation of heart, and irregularity of bowels disappear under training, but if they exist, the regimen should be entered upon with more than usual caution.

An important modification of training is that which contemplates the reduction of CORPULENCE (q v), which has increased to the extent of interfering with comfort and preventing active exercise. If an exhausting amount of muscular effort is enforced, the digestion of meat is interfered with, while at the same time there still goes on the absorption of such fat as is unavoidably present in the victuals, so that the muscles and nerves lose strength, while the adipose tissue grows. Besides this, if by violent means the weight is worked down, then, to keep it down, those violent means must be persisted in, and if they be neglected for more interesting occupations, the burden rapidly increases to a greater degree than ever. Many uncomfortably obese persons are very active in mind and body, and could not add to their muscular exercise without risk of harm.

Regimen, then, is more essentially important to them than to other trainers, and they will probably be more induced to attend to it if they understand the principles on which it is based. This is simply to exclude from the bill of fare all those articles which contain fat or which by the chemical actions of the digestive viscera may be converted into fat.

For the reduction of corpulence the following rules may be observed for a three weeks' course:—

Rise at 7, rub the body well with horse-hair gloves, have a cold bath, and take a short turn in the open air. Breakfast (alone) at 8 or 8 30, on the lean of beef or mutton (cutting off the fat and skin), dry toast, biscuit or oat cake, a tumbler of claret and water, or tea without milk or sugar, or made in the Russian way with a slice of lemon. Lunch at one on bread or biscuit, Dutch cheese, salad, water-cresses, or roasted apples, hung beef or anchovies, or red-herring, or olives, and similar relishes. After eating, drink claret and water, or unsweetened lemonade, or plain water, in moderation. Dine at any convenient hour. Avoid soup, fish, or pastry, but eat plain meat of any sort except pork, rejecting the fat and skin. Spinach, haricots, or any other green vegetable may be taken, but no potatoes, made dishes, or sweets. A jelly, or a lemon-water-ice, or a roast apple, must suffice in their place. Take claret and water at dinner, and one glass of sherry or Madeira afterwards.

Between meals, as a rule, exercise must always be taken to the extent of inducing perspiration. Running, when practicable, is the best form in which to take it.

Seven or eight pounds is as much as it is prudent to lose during the three weeks. If this loss is arrived at sooner, or indeed later, the severe parts of the treatment may be gradually omitted, but it is strongly recommended to modify the general habits in accordance with the principle of taking as small a quantity as possible of fat and sugar, or of substances which form fat and sugar, and sustaining the respiratory function. By this means the weight may be gradually reduced for a few months with safety.

Small quantities of dilute alcoholic liquids taken with meals slightly increase the activity of the renewal of the nitrogenous tissues, mainly muscle, that is to say, there is a more rapid reconstruction of those parts, as is shown by the augmented formation of urea and the sharpened appetite. Life is fuller and more complete, old flesh is removed and food appropriated as new flesh somewhat more quickly, than when no alcohol is ingested. There appears to be a temporary rise in the digestive powers of the stomach, which is probably the initiative act. The

nerve functions are blunted, and a lessened excretion of phosphorus exhibits a temporary check in the wear and renewal of the nerve tissue. The "vital capacity" of the lungs, as indicated by the spirometer, is reduced, showing a diminished oxidation of the blood.

The effect on a healthy man of taking with a meal such a quantity of fermented liquor as puts him at ease with himself and the world around, without untoward exhilaration, is to arrest the wear of the nervous system, especially that part employed in emotion and sensation. Just as often, then, as the zest for food is raised to its normal standard by a little wine or beer with a meal, the moderate consumer is as much really better as he feels the better for it. Where the food is as keenly enjoyed without it, the consumption of a stimulant is useless. But alcohol is not a source of force, and its direct action is an arrest of vitality.

Diet for Mental Work—An expression of Büchner's—"No thinking without phosphorus"¹—has gained an unhappy notoriety. Strictly speaking, it is a groundless assumption, for we cannot say that intellectual being may not exist joined to any form of matter, or quite independent of matter. We certainly do not know enough of the subject to lay down such a negative statement. And if it be held to mean that the amount of phosphorus passing through the body bears a proportion to the intensity of thought, it is simply a mis-statement. A captive lion, tiger, leopard, or hare assimilates and parts with a greater amount of phosphorus than a hard-thinking man; while a beaver, noted for its powers of contrivance, excretes so little phosphorus that chemical analysis cannot find it in the excreta. All that the physiologist is justified in asserting is that for the mind to energize in a living body that body must be kept living up to a certain standard, and that for the continuous renewal of life a supply of phosphatic salts is required. The same may be said with equal justice of water, fat, nitrogen, chloride of sodium, oxygen, &c. The phosphates are wanted indeed, but wanted by pinches, whereas water is required by pailfuls. A few days without water, or a few minutes without oxygen, will terminate the train of consciousness. The practical points taught us by physiology are that for the integrity of thought integrity of the nervous tissue is requisite, and for the integrity of the nervous tissue a due quantity of such food as contains digestible phosphatic salts.

The most perfect regimen for the healthy exercise of thought is such as would be advised for a growing boy, viz., frequent small supplies of easily soluble mixed food, so as to furnish the greatest quantity of nutriment without overloading the stomach, or running the risk of generating morbid half-assimilated products. For it is essential to the intellectual direction of the nervous system that it should not be oppressed by physical impediments. The presence in the stomach or blood of imperfectly assimilated nutriment impedes its functions in close proportion to their amount, so that not only the constituents, but the mode of administering food, must come into the calculation. "*Repletus venter non studet libenter*," is an old proverb, the application of which saves many a brain and many a stomach from being worked against the grain. Rest from brain-work for twenty minutes before meals, entire abstinence from it during meals, and rest again till the weight has passed from the stomach, are essential to the reconciliation of psychical exertion with bodily health.

The physiology of the action of alcohol has a very important bearing on the physical management of the mental functions. Alcohol has the power of curbing, arresting, and suspending all the manifestations of the

¹ Ohne Phosphor kein Gedenke. *Kraft und Stoff*, sect. 122.

nervous system, so that we feel its influence on our thoughts sooner than on any other part of the system. Sometimes it brings them more completely under our command, controls and steadies them; more often it confuses or disconnects them, and then breaks off our power over them altogether. When a man has tired himself by intellectual exertion, a moderate quantity of alcoholic stimulant taken with food acts as an anæsthetic, stays the wear of the system which is going on, and allows the nerve force to be turned to the due digestion of the meal. But it must be followed by rest from toil, and is in essence a part of the same treatment which includes rest—it is an artificial rest. To continue to labour and at the same time to take an anæsthetic is a physiological inconsistency. The drug merely blunts the useful feeling of weariness, and prevents it from acting as a warning. There is no habit more fatal to a literary man than that of taking stimulants between meals; the vital powers go on wearing out more and more without their cry for help being perceived, and in the end break down irrevocably.

As to quantity, the appetite for solid food is the safest guide. If a better dinner or supper is eaten when it is accompanied by a certain amount of fermented liquor, that is the amount most suitable; if a worse, then an excess is committed, however little be taken.

The aim of the diet should be (to quote the words of John Milton) "to preserve the body's health and hardness, to render lightsome, clear, and not lumpish obedience to the mind, to the cause of religion and our country's liberty, when it shall require from hearts in sound bodies to stand and cover their stations."

It is especially when the mind of genius is overshadowed by the dark clouds of threatened insanity, of hypochondriasis, or of hysteria, that a rational mode of life preserves it. Nothing but daily exercise, temperate meals, and a punctual observance of regular hours of rest and study could have kept burning the flickering reason in poor Cowper.

As regards the proper quantity of alcohol that may be used the two following questions naturally occur—How is a man to know when he has had enough? and what are the signs of too much? The ancients used to wear dark red or purple engraved gems, which they considered preservatives against excess, and called them *ἀνέθυστοι*, "sober-stones," "amethysts." The name is now limited to the violet rock crystal, but in early times it was applied to several other stones, cut in intaglio, and worn on the fingers at festive gatherings. So long as the wearer could decipher the minute works of art they bore, he had not reached excess. A more delicate test still is the appreciation of temperature by the skin; if a draught does not chill, if a hot room fails to produce the usual discomfort, the wise man knows he has exceeded and must stop at once. In short, the safest rule is that when there is a consciousness of any psychical effect at all beyond that of satisfaction at the relief of bodily weariness—such a satisfaction as is felt on taking a good meal by a vigorous person—then the limits of moderation have been attained. On ordinary occasions of daily life, and "for the stomach's sake," no more should be taken. Each fresh drop is a step downwards to the evil results of alcohol. But to the practiser of daily temperance, festive occasions are safe and may be beneficial. A man may from time to time keep up without harm the above mentioned sense of satisfaction by good and digestible wine in good company without fear of getting drunk or failure of health, if he makes it a law to himself to stop as soon as he experiences any hurry of ideas or indistinctness of the senses.

Diet of Mothers—During pregnancy as much care should be taken not to get too fat as is taken by an athlete

training for a race. The rules for modified training explained above will afford hints on the subject, but it is not desirable to carry the process so far.

There is a temptation at this time to increase the usual allowance of stimulant; alcohol is taken between meals to overcome the nausea and depression incident to the state of body. And by this mistaken expedient the nausea gradually becomes dyspeptic vomiting. On leaving it off the sickness ceases. A mother should also remember that nearly all the alcohol she consumes mixes with her blood, which now is one with the blood of the foetus.

During lactation the most suitable drink for a mother is cow's milk, fresh and unskimmed. If it turns sour on the stomach, lime-water mixed with it not only corrects the acescence, but also supplies a valuable aid to the growing bones of the infant. In her solid dietary also milk may be fairly taken as the type of a due admixture of alimentary principles, because it is not individual growth, or the production of muscular force, but the secretion of milk, that is the object of the selection of diet.

Supposing the full diet to consist of three pounds of solid food, that will require six pints extra of uncombined aqueous fluid to make it as fluid as milk; and, to combine the nitrogenous and carbonaceous constituents in due proportion, the three pounds of solid food should consist of

14½ oz. of meat
18 oz. of fat, butter, and sugar
20 oz. of farinaceous food and vegetables.
¾ oz. of salt, lime, &c.

At first, from the exhaustion consequent on childbed, from the want of exercise and of fresh air, the appetite turns against meat. Let then milk, especially boiled milk with arrowroot or the like, chicken broth, or egg custards, fill up the deficiency.

Any increase in the habitual allowance of alcohol is as unfitting to this period of life as during pregnancy.

Diet of Old Age.—It is a remark extant from the rough times when famine was more frequent than now, that the older a human being is the better deficiency of food is borne. Old men suffer least from abstinence,¹ and benefit therefore most from temperance in eating. Everybody who has passed the age of fifty, or thereabouts, with a fairly unimpaired constitution, will act wisely in diminishing his daily quantity of solid food. There is less demand for the materials of growth, and consequently animal food should bear a smaller proportion than heretofore to vegetable, and it is mainly in that ingredient of the diet that reduction should be effected. Neglect of this rule in declining years is often punished by gout, a disease attributable to excess of nitrogenous aliment, and for this reason common in elderly men.

In the autumn of life the advantages derived from fermented liquor are more advantageous, and the injuries it can inflict less injurious to the body than in youth. The effect of alcohol is to check the activity of destructive assimilation, to arrest that rapid flux of the substance of the frame which in healthy youth can hardly be excessive, but which in old age exhausts the vital force. Loss of appetite is a frequent and a serious symptom in old age. It usually arises from deficient formation of gastric juice, which, in common with other secretions, diminishes with years. It is best treated physiologically rather than by drugs.

Diet in Sickness.—In all that has gone before health has been presupposed. The modifications necessitated by sickness are of three kinds—first the avoidance of such articles of consumption as would increase the disease under the special circumstances, although ordinarily wholesome; second, the maintenance of the functions

¹ Hippocrates, *Aphorism* xiii.

or parts of the frame which remain normal; third, the administration, for a special curative purpose, of peculiar food which would not be recommended for general use.

In all fevers, which are classed together as being apparently due to a poison multiplying itself in the blood, the art of diet consists in giving an almost continuous supply of liquid nutriment, holding very soluble aliments in a dilute form. There is nothing so digestible as water, and we take advantage of this high digestibility to get whatever it can dissolve digested along with it. For the first three or even four days patients previously strong should have only farinaceous food, well boiled and cooled to the temperature of the body. Evidence has been already quoted of the power which oatmeal gruel possesses of sustaining force under the trying circumstances of excessive toil. Now, fever closely resembles muscular effort in its arrest of the digestive functions, at the same moment that it makes an urgent demand for nutriment. With ultra-Egyptian rigour, while straw is withheld, "the tale of the bricks is doubled," and we know by the quantity of urea and phosphates in the urine, and by the fecal excretion, that the muscles and nerves of the bed-ridden sufferer are melting away as fast as if he were scaling the Alps with nothing to eat. It is quite reasonable to transfer the experiences derived from health to sickness, and to feel satisfied that we are not wasting precious opportunities when we are giving fever patients such a time-honoured diet as oatmeal gruel, care being taken that it is thoroughly well boiled. After three days the tissues are beginning to suffer, and it is advisable to add chicken broth, meat jelly, and strong soup. Let that be supplied which the emaciation shows to be passing away—nitrogenous tissue.

The administration of alcohol is to be regulated partly by the temperature and partly by the condition of the nervous system. Usually if the heat of the blood (as taken at the axilla) is above 103° , and always if it is above 105° , there is a necessity for it. Again, if there is great prostration of strength, or tremor of the hands, or quivering in the voice and respiration, if there is low muttering delirium when the patient is left quiet, it is required.

Green-sickness, or *anæmia*, is characterized by the rapid disappearance of the red particles which float in the blood. To what a strange extent this goes may be seen by looking at the insides of the lips, which naturally hold such a quantity of the fluid as to be quite scarlet, but which now are pale like those of a corpse. It is calculated that the loss of material in marked cases of green-sickness may amount to three pounds of this important constituent of the blood.¹ Yet it is capable of complete renewal by diet. If by dint of remedies, notably iron, the appetite can be so regulated as to enjoy meat in excess of the immediate wants of the body, that meat is converted into hematin, and the healthy hue returns to the cheeks as quickly as it left. Wine is useful at meals on account of the stimulus it gives to the appetite, it is injurious between meals by spoiling it.

Acute rheumatism and *acute gout* are best treated on an opposite principle. A nutrient nitrogenous diet, which the patient assimilates only too readily, retards recovery, and will even bring on a relapse during convalescence. If meat in any form, solid or liquid, be eaten, it seems to turn into acid, which is already in excess in the blood. The power of fully converting it into living flesh is wanting, and until this power is regained a semi-conversion into an organic acid takes place. The redder and more muscular the meat is, the more it disagrees.

Chronic gout is indubitably due to good cheer indulged in, either by the sufferer or his ancestors. When a man day after day swallows more nitrogenous food than is wanted

for the repair of his tissues, the following results may be expected, with variations dependent upon his original constitution. If the digestive solvents are weak and scanty, the excess passes through the canal in an undigested state, and is partially decomposed there. Thereon ensue all sorts of abdominal derangements, which, however, have the advantage of getting rid of the offending matters. If, on the other hand, the stomach secretes vigorously on being stimulated, then indeed the excess is digested and absorbed, and is subject to the future changes consequent on assimilation. An active out-of-door life neutralizes this in some measure by augmenting oxidation; much of the albumen goes to form glycogen, and acts as a fuel for the maintenance of muscular force. The balance is wasted in an unexplained way, and does not necessarily injure a hardy frame. The violent muscular exertion and high training needful for oxidation being inconsistent with the habits of intellectual society, a man in the prime of life who puts too much meat into a good stomach habitually retains in his blood an excess of uric acid, into which the nitrogenous waste converts itself. Uric acid in the blood has been distinctly traced as the essence of gout. Perhaps this imaginary first offender develops the full consequences; and that is the best thing that can happen, inducing greater carefulness in future.

These views can suggest but one line of preventive treatment. The children of gouty families should be brought up to a life of strict abstemiousness and muscular activity. From the earliest years vegetables and "meagre" soups should form a considerable portion of their dietary.

Gouty adults require meat but once in twenty-four hours. The bill of fare should be varied from day to day, but as simple as possible at each meal. Rich sauces are to be eschewed, and a lemon, an infusion of herbs and pepper, bread-sauce, or a purée of vegetables, adopted in their place. Sngar at the end of meals generates an excess of organic acid, and is to be avoided, if cheese is eaten it should be new, and is best toasted and creamed.

Dilute alkaline waters containing soda, such as Apollinaris or the weaker Vichy, are a rational drink during meals; but it is probably best to keep to pure water. Those who live idle lives require no alcohol; and it should not be an habitual accompaniment to meals.

Red gravel is evidence of a constitution so closely allied to gout, that nothing need be said further about its appropriate regimen.

In *Bright's disease* of the kidneys, in *contracted liver*, and in short in all degenerative lesions, alcohol has a baneful influence. Its action upon the tissues is directly the same as theirs. Moreover, if we agree with its latest expositor, Dr Sibson, that Bright's disease is closely associated with increased arterial tension, alcohol (whose effect is also to increase tension) must be peculiarly poisonous.²

For the cure of these diseases, independent of the nutrition of the rest of the body, a milk diet has been proposed, and it seems to offer a fair prospect, if the patients can be persuaded to persist in it. How safely a milk diet may be adopted in middle life is shown by the example of Dr Cheyne, a Bath physician of the last century, who at about fifty-five restricted himself entirely to milk and biscuits, and yet was able to fulfil the duties of his laborious profession. He took at first of the former six pints, of the latter twelve ounces, but he shortly diminished the quantity to half, and after sixteen years' experience found it fully sufficient, and indeed capable of further reduction in quantity.³

Weak and slow digestion is a condition which enforces an

² Sibson's Harveian Lectures, *British Med. Jour.*, Feb 10, 1877

³ *The Natural Method of Curing Diseases of the Body*, &c, by Geo. Cheyne, M.D. 1742.

¹ Chambers's Lectures, chiefly Clinical. Lect. II.

especial care for meat and drink. The cause of the imperfection lies in a deficiency in the supply of nerve power to the stomach, so that it both secretes its solvent fluid and also rotates its contents too slowly; and the more it is loaded the slower it goes. Of the medicinal means of curing such a state this is not the place to speak; but none of them will avail without the aid of a rational dietary. Time must be given to the oppressed organ wherein to empty itself of every complete meal, and such a period of rest given as will allow of the recovery of force; or if the meals are frequent they must be very sparing. The observations of Busch (Virchow's *Archiv.* xiv.) show that a period of five hours elapses in the healthy subject before a fully filled stomach can empty itself, and in the dyspeptic the process is still longer. Whenever, therefore, the organ is loaded as healthy people rightly load it, a man should allow at least seven or eight hours to elapse before sitting down to another meal. And he must never eat till the need for food is announced by appetite. Perhaps a more generally applicable and easier obeyed law is not to make full meals at all, but to stop short at the feeling of repletion, and, when that has gone off, again to take in the supply allowed by circumstances. Three moderate meals are usually sufficient to keep up the strength.

Meat should be once cooked. Mutton, feathered fowl, venison, lamb, and beef are digestible in the order they here are placed in. The more difficult dishes should have the longest time allowed to them. Of the farinaceous articles of diet, bread and biscuits are the most easily penetrated by the gastric juices, and all their preparations are safe. The best bread is the "aerated," which is free from decomposing yeast. Macaroni is good if soaked till quite macerated. Pastry is difficult of solution. Vegetables are very necessary; cauliflowers, Jerusalem artichokes, beetroot, French beans, soft peas, stewed celery, turnip-tops, spinach, are the most readily disposed of.

When the usual mixture of meat and vegetables is found to induce flatulence, it is a good expedient to eat vegetables only at one meal and meat and bread only at another. The principle on which this plan is based is that starchy food is dissolved mainly by the alkaline saliva, whereas meat is dissolved by the acid gastric juice. In a vigorous person both these are copious enough to render immaterial their mutual neutralization, but when they are scanty, their separate employment is a physiological economy.

Consumption is a disease whose treatment is almost wholly dietetic. The children of a mother whose pedigree exhibits proof of a consumptive tendency may with propriety be put to a healthy wet nurse immediately on birth, and, on being weaned, be fed from a Channel Island cow. The milk should be boiled and then cooled down to tepidity. A small tea-spoonful of "saccharated solution of lime" may be advantageously added to each quart of milk when the coming teeth require the elements of their nutrition to be added to the diet. The rules already given for the healthy management of the young should be adhered to with unusual strictness, and any departure from them should be made only to provide for some peculiar necessity of the case according to medical advice.

In cases of consumption it is difficult to say that drugs are useless, but certainly those that come nearest to aliments have most evidence in their favour, such as iron, cod-liver oil, and the phosphates of lime. Their effect on the appetite must be sedulously watched, and the end must not be sacrificed to the means; that is to say, if they spoil the appetite, they must be left off. The reason for administering oil is to afford an easily assimilated basis of renewed organic growth, to take the place of the abnormal tendency to form tubercular matter. If anything pre-

vents its easy assimilation it is obviously useless. The use of climate in the treatment of phthisis may be tested by its dietetic action; if it improves the appetite, it is doing good; if it injures the appetite, it is doing harm.

In *chronic jaundice* the function of the liver is best restored by the free use of green vegetables at all meals.

Diabetes, when it has once assumed a chronic form, is never really cured, but life may be much prolonged by the employment of a diet from which sugar and starch are excluded as far as practicable, and the patient nourished on animal food. The best fare for diabetic patients is that given by Professor Bouchardat in his work *Du Diabète sucré*, Paris, 1852.

In *functional nervous diseases*, such as hysteria and hypochondriasis, the appetite, muscular elasticity, and mental powers will often be observed to be deficient in the early part of the day, and to recover their tone in the evening. At this latter time, therefore, it is advisable to make the principal meal.

Scurvy is a notable example of a disease of which, more than any other, the prevention depends on the adoption of a suitable diet. Its symptoms so far resemble those of general starvation that from the earliest time of its appearance in history it has been suspected that it is due to a dietary defective in some necessary ingredient; and practical observation soon showed that this was fresh vegetables. It was found on every long voyage that the crew suffered from scurvy in proportion to the length of time they were restricted to dry food, and that they recovered rapidly as soon as they got access to a supply of succulent plants. This requisite for health is obviously the most difficult of all things to procure aboard ship, and efforts were made to find a substitute capable of marine transport. From the time of Hawkins¹ (1593) downwards the opinion has been expressed by all the most intelligent travellers that a substitute is to be found in the juice of fruits of the orange tribes, such as oranges, lemons, &c. But in its natural state this is expensive and troublesome to carry, so that skippers and owners for a couple of centuries found it expedient to be sceptical. The pictures of scurvy as it appeared during the 18th century are horrible in the extreme. But the statute of 1795, passed through the exertions of Captain Cook and Sir Gilbert Blane, has enforced the carrying of lime-juice. This invaluable preventive has shown its influence all the more decidedly by the disease still appearing occasionally under strong promoting circumstances, and to a certain extent in spite of the antidote, but it is so modified as to be usually more of the nature of a warning or demonstration than of a serious invasion. Some indeed have questioned and even denied altogether the blessings derived from the enforced use of lime-juice. But they make a very scanty show when weighed with those whom they undertake to oppose, and it is superfluous here to enter into the arguments and results of observation constituting the ponderous *Report of the Committee appointed by the Lords Commissioners of the Admiralty to Enquire into the Causes of the Outbreak of Scurvy in the recent Arctic Expedition, &c, and presented to both Houses of Parliament, May 7th 1877*, which seems to settle for ever the preventive powers against scurvy of the use of lime-juice.

The committee alluded to was appointed in consequence of one of those exceptional outbreaks of scurvy induced by exceptional circumstances. The ships sent on the exploring expedition of 1875 were amply provided with lime-juice, and with printed expositions of its value. During the voyage out and in the long inaction of the winter the men's health was so well preserved by general attention to

¹ Sir Rd. Hawkins's *Voyage*, edited by Hakluyt Society, p. 60

hygiene that no cases of even mild scurvy were detected; the pallor and languor and depression of spirits of some among the sailors were attributed to the want of sunlight for 142 days, and it was expected that a few days sledge travelling in the open air would reinvigorate them. There was plenty of lime-juice aboard; but it seems that it is not the custom to add to the weight of provisions, which Polar sledging parties have to propel, by including the preservative amongst them. Sir George Nares, the commander of the expedition, cites the names of 10 admirals, 10 doctors, and 15 captains who have conducted land explorations in this fashion without it; and they returned unscathed to any serious extent. But on this recent occasion the crews seem to have been peculiarly predisposed to illnesses of scorbutic nature by the more than ordinary scarcity of fresh meat in their dietary, arising out of the deficiency of game in the extremely high latitude where they wintered. With few exceptions the whole of the crews of the "Alert" and the "Discovery" were employed in sledging, and the consequence was, that of the 122 officers and men, 59 were more or less incapacitated by scurvy, and 4 died.

The real reason for not carrying lime-juice in such expeditions is its cumbersomeness. Including bottles, though in truth they are not wanted in a hard frost, it may be said that 1 lb a week for each man would have to be added to the baggage,¹—a serious item, no doubt. And with a view of remedying the inconvenience, medical men have long sought to discover to what constituent of the complicated mixture afforded by nature it is that it owes its efficacy. In a contribution to the *Medico-Chirurgical Review* for 1848, Dr Parkes examined exhaustively the evidence concerning the various deficiencies in ship food as compared with fresh food which might be filled up by one or other of the components of lime-juice; and by exclusion he is led to the conclusion that the cause of scurvy is to be found in deficiency of salts whose acids form carbonates in the system, viz., citric, tartaric, acetic, lactic, and malic acids.

Though not so good as when in their natural form, because less digestible and pleasant, yet a supply of citrates, tartrates, lactates, and malates of potash might be packed in small bulk, and, under circumstances where weight is of importance, might take the place of lime-juice. Or bologenges might be made of lime-juice freed from its aqueous portion and preserved with sugar. Three or four of these a day might be easily swallowed without stopping work.

Before leaving the subject of maritime scurvy, it may be suggested how useful it would be if those who sail in desolate regions were to carry seeds of antiscorbutic vegetables, which, strewn broadcast in uninhabited places, would form a flora capable of saving the lives of many a wrecked or weather-bound crew.

Scurvy, as landsmen see it in time of peace, amounts to little more than anæmia with a softening and bleeding condition of the gums. But it indicates the use of exactly the same preventives and remedies as the more severe complaint.

Starvation is a disease which it is a platitude to say may be prevented by diet; nevertheless there are connected with it a few peculiarities of scientific and practical interest which may not be unworthy of notice. "Inedia," as it is called in the nomenclature of diseases by the London College of Physicians, is of two kinds, arising from *want of food* and from *want of water*.

When entirely deprived of nutriment the human body is capable of supporting life under ordinary circumstances for little more than a week. In the spring of 1869 this was

tried on the person of a "fasting girl" in South Wales. The parents made a show of their child, decking her out like a bride on a bed, and asserting that she had eaten no food for two years. Some reckless enthusiasts for truth set four trustworthy hospital nurses to watch her; the Celtic obstinacy of the parents was roused, and in defence of their imposture they allowed death to take place in eight days. Their trial and conviction for manslaughter may be found in the daily periodicals of the date; but, strange to say, the experimental physiologists and nurses escaped scot-free. There is no doubt that in this instance the unnatural quietude, the grave-like silence, and the dim religious light in which the victim was kept contributed to defer death.

One thing which remarkably prolongs life is a supply of water. Dogs furnished with as much as they wished to drink were found by M. Chossat (*Sur l'Inanition*, Paris, 1843) to live three times as long as those who were deprived of solids and liquids at the same time. Even wetting the skin with sea-water has been found useful by shipwrecked sailors. Four men and a boy of fourteen who got shut in the Tynewydd mine near Porth, in South Wales, in the winter of 1876-7 for ten days without food, were not only alive when released, but several of them were able to walk, and all subsequently recovered. The thorough saturation of the narrow space with aqueous vapour, and the presence of drain water in the cutting, were probably their chief preservatives,—assisted by the high even temperature always found in the deeper headings of coal mines, and by the enormous compression of the confined air. This doubtless prevented evaporation, and retarded vital processes dependent upon oxidation. The accumulation of carbonic acid in the breathed air would also have a similar arrestive power over destructive assimilation. These prisoners do not seem to have felt any of the severer pangs of hunger, for they were not tempted to eat their candles. With the instinctive feeling that darkness adds a horror to death, they preferred to use them for light.

It is a paradoxical fact, that the supply of the stomach even from the substance of the starving individual's body should tend to prolong life. In April 1874, a case was recorded of exposure in an open boat for 32 days of three men and two boys, with only ten days provisions, exclusive of old boots and jelly-fish. They had a fight in their delirium, and one was severely wounded. As the blood gushed out he lapped it up; and instead of suffering the fatal weakness which might have been expected from the hemorrhage, he seems to have done well. Experiments have been performed by a French physiologist, M. Anselmier (*Archives Gén. de Médecine*, 1860, vol. i. p. 169), with the object of trying to preserve the lives of dogs by what he calls "artificial autophagy." He fed them on the blood taken from their own veins daily, depriving them of all other food, and he found that the fatal cooling incident to starvation was thus postponed, and existence prolonged. Life lasted till the emaciation had proceeded to six-tenths of the animal's weight, as in Chossat's experiments, extending to the fourteenth day, instead of ending on the tenth day, as was the case with other dogs which were not bled.

These instances of the application of the art of dietetics to the treatment of disease are sufficient to show the principles which should be kept in sight. The pathology of the ailment should be considered first, then its bearing upon the digestive organs, and lastly the bearing of the digestive organs upon it.

And before quitting the subject of health as affected by diet, the common-sense hint may be given to those who are in good sanitary condition, that they cannot do better than let well alone. The most trustworthy security for future health is present health, and there is some risk of overthrowing nature's work by overcaring.

¹ In merchant ships lime-juice is used during Polar service in a ration of an ounce daily. See "Report" above cited. But the opinions of the officers examined seems to agree that the quantity is not sufficient, and advise half as much again or more.

Pleasure as an object of Dietetics.

The social importance of gratifying the palate has certainly never been denied in practice by any of the human race. Feasting has been adopted from the earliest times as the most natural expression of joy, and the readiest means of creating joy. If ascetics have seemed to put the pleasure away from them, they have done so in the hope of purchasing by their sacrifice something greater and nobler, and have thus tacitly conceded, if not exaggerated, its real value. Experience shows that its indulgence, unregulated by the natural laws which govern our progress in civilization, leads to unutterable degradation and meanness, brutalizes the mind, and deadens its perception of the repulsiveness of vice and crime. But that is no cause why this powerful motive power, governed by right reason, should not be made subservient to the highest purposes.

The times of meals must be regulated with a regard to the disposal of the remainder of the day, whether that depends on choice or on necessity. Violent exertion of either mind or body retards digestion; and therefore, when this is practised, food is not called for so soon as on a day of rest. The heaviest meal should be postponed till the day's work is done; it is then that social homo joys give the requisite repose to the body and mind. Light eaters may dine as late as they please, but those of larger appetite should lengthen the interval between their repast and bed-time. After the night's sleep and the long fast which has emptied the digestive canal of its nutritive contents, a breakfast should be taken before any of the real business of life be begun. It is no proof of health or vigour to forego it without inconvenience; but it is proof of health and vigour to be able to lay in then a solid foundation for the day's labour. Not less than four and not more than six hours should elapse before the store is again replenished. A light farinaceous lunch with vegetables and fruit may be made most appetizing, and is followed by a cheerful afternoon, whereas a ponderous meat and wine meal entails heaviness of spirit.

Diet in relation to Economy.

Due Proportion of Animal and Vegetable Food—It has been taken for granted thus far, that the mixed fare, which has met the approval of so many generations of men, is that which is most in accordance with reason. But there are physiologists who argue that our teeth resemble those of the vegetable-feeding apes more than those of any other class of animal, and that therefore our most appropriate food must be of the fruits of the earth¹. And if we were devoid of the intelligence which enables us to fit food for digestion by cookery, it is probable no diet would suit us better. But our reason must not be left out of account, and it is surely quite as natural for a man to cook and eat every thing that contains in a convenient form starch, fat, albumen, fibre, and phosphorus, as it is for a monkey to eat nuts or an ox grass. The human race is naturally omnivorous.

Moreover, man is able not only to develop his highest faculties and perform all his duties on any form of digestible aliment, but he is also very much to diminish the requisite quantities by a due admixture. The diet which supplies the demand most accurately will be the most economical in the highest sense. And that this diet is a mixed one can be shown by the following method of calculation. We can measure by experiment the ultimate elements of all that is thrown off from the body as the result of vital decomposition, the ashes, the smoke, and the

gases which the fire of life produces; and thus we can lay down a rule for the minimum quantity of those elements which the daily food must contain to keep up the standard weight. If the diet be such as to make it necessary to eat too much of one element in order to secure a sufficient amount of another, there is a waste, and the digestive viscera are burdened with a useless load. But there is no single article procurable for the food of the adult population which presents the exact proportion of elements required by an adult, and therefore no single article alone can supply human wants without waste.

As an example, apply this reckoning to the elements carbon and nitrogen, which constitute the main bulk of the solids in our food and in our bodies. Suppose a gang of 100 healthy prisoners to excrete, in the shape of breathed air and evacuations, $71\frac{1}{2}$ lb of carbon and $4\frac{1}{2}$ lb of nitrogen (which is pretty nearly the actual amount of those elements in the dried solids of the secretæ, as estimated by current physiological works). Both nitrogen and carbon to that extent must of course be supplied in the food. Now, if you fed them on bread only, there would be wanted daily at least 380 lb of it to sustain them alive long, for it takes that weight to yield the $4\frac{1}{2}$ lb of nitrogen daily excreted; while, in the 380 lb of bread there are 128 $\frac{1}{2}$ lb of carbon, which is 57 lb above the needful quantity of that substance².

If, on the other hand, the bread were replaced by a purely animal diet, there would have to be found 354 lb of lean meat in order to give the $71\frac{1}{2}$ lb of carbon, and thus there would be wasted 105 lb of nitrogen contained in the meat, over and above the $4\frac{1}{2}$ lb really required to prevent emaciation.³

In the first case each man would be eating about 4 lb of bread, in the second $3\frac{1}{2}$ lb of meat *per diem*. If he ate less, he would lose his strength. The first would carry about with him a quantity of starch, and the last a quantity of albuminous matter not wanted for nutrition, and would burden the system with an useless mass very liable to decompose and become noxious.

When work is undertaken, much more is actually wanted. According to Mr Vizetelly, the labourer in a Spanish vineyard consumes daily between 8 and 9 lb of vegetable food, consisting of bread, onion-porridge, and grapes⁴. And when animal food alone is taken, as in the case of the Esquimaux, 20 lb of it a day is the usual allowance.

Now, if a mixed dietary be adopted for the gang of 100 prisoners before mentioned, 200 lb of farinaceous food, with 56 lb of animal muscle, would fulfil the requirements of the case; 2 lb of bread and a little more than $\frac{1}{2}$ lb of meat a head would be enough, under ordinary circumstances, for each man's daily food.

200 lbs of bread contains . . .	60 of carbon,	2 of nitrogen
60 lbs of meat (including 12 $\frac{1}{2}$ lbs. of fat on it), contains	12 "	2 $\frac{1}{2}$ "
	72	4 $\frac{1}{2}$

Balance of Food and Work.—The most important modification to be made in the above estimate arises from the differences of work demanded. Men may exist in inaction on a scale of food supply which is followed by death from starvation when they are put to hard labour. It is of importance, therefore, to have some measure of the effects of physical exertion. And here mechanical science has con-

² Dr Letheby's analysis gives 8.1 per cent of nitrogenous matter to bread (*Lectures on Food*, p. 6). Of this $\frac{3}{4}$ th is nitrogen. Berthollet's analysis of gluten giving 14.60 per cent (*Annales de Chim. et Phys.*, lxi. 229). M. Payen makes the proportion of nitrogen to carbon in bread as 1 to 30.

³ The proportion of nitrogen to carbon in albumen is as 1 to 3 $\frac{1}{2}$ (15.5 to 53.5 by Mulder's analysis, quoted in *Laboratory of Chemistry*, i. 343). In red meat there is 7.4 per cent of water to the lb (50).

⁴ *Facts about Sherry*, chap. i. 1876, and Sir John Roebuck's *Journal of a Voyage for the Discovery of the North-West Passage*, i. 415.

¹ Milne-Edwards, *Cours de Physiologie*, vol. vi. p. 198.

tributed to physiology a precision rarely attainable in our dealings with social economy. Mr Joule of Manchester analyzed, about thirty years ago, the relation which the heat, used as a source of power in machinery, bore to the force of motion thus made active. He showed that raising the temperature of 1 lb of water 1° Fahr. was equivalent to raising 772 lb to the height of 1 foot; and conversely, that the fall of 772 lb might be so applied as to heat 1 lb of water 1° Fahr. Thus, the mechanical work represented in lifting 772 lb 1 foot, or 1 lb 772 feet, forms the "dynamic equivalent," the measure of the possible strength of 1° of temperature as marked by the thermometer in 1 lb of water. Physiologists seized eagerly on the opportunity which Joule's demonstration seemed to afford them of estimating in actual numerals the relation of living bodies to the work they have to do. So much earth raised on an embankment represents so much heat developed in the machinery, be it living or dead. The fully digested food, converted through several stages into gaseous, liquid, and solid excretory matters, produces by its chemical changes a definite amount of heat, of which a definite amount escapes and a definite amount is employed in working the involuntary machinery of the body, and the rest is available for conversion at will into voluntary muscular actions.

It may be reckoned that the daily expenditure of force in working the machinery of the body—in raising the diaphragm about 15 times and contracting the heart about 60 times a minute, in continuously rolling the wave of the intestinal canal, and in various other involuntary movements, without anything to be fairly called work.—it may be reckoned that the expenditure of force in doing this is equal to that which would raise a man of 10 stone 10,000 feet.

There are several reasons for believing that in assigning their physiological functions to the several sorts of food, nearly all the business of begetting force should be ascribed to the solid hydrocarbons, starch and oil, by their conversion into carbonic acid and water, just as there are good grounds for thinking that it is the conversion of the solid hydrocarbon of coal into the same substances which drives a locomotive. To the nitrogenous aliments seems allotted primarily the task of continuously replacing the wear and tear of the nitrogenous tissues, while any excess of them assists the starch and oil in keeping up the animal heat.

One of the most cogent of the reasons for this view is that the chief nitrogenous excretion, the urea, is not increased in amount in proportion to the work done, as shown by the experiments of Messrs Fink and Wiselenus; whereas the excretion of carbonic acid in a decided manner follows the amount of muscular exertion. Now, it is very clear that if the supply of power to do work depended on the decomposition and renewal of the muscles by flesh food, the urea must be exactly proportioned to the exertion, which is not the case.

To give an example of the mode of working out a problem by this theory. Professor Frankland, in a series of experiments made in 1866 at the Royal Institution, and published in the *London Philosophical Magazine*, vol. xxxii. p. 182, ascertains with the "calorimeter" (which reckons the amount of heat evolved as a thermometer does its degree) the quantity of energy or force evolved under the form of heat during the oxidation of a given weight of alimentary substance. It has been explained that heat and mechanical work, being convertible into one another, bear a constant proportion to one another; so that a definite production of so much heat invariably represents the potentiality of so much motion, used or wasted according to circumstances. From the reading of the calorimeter therefore may be calculated how many extra pounds ought to

be raised a foot high by a man who has eaten an extra pound of the food in question; how many steps a foot high he ought to raise a weight of ten stone (say himself) before he has worked out the value of his victuals. Professor Frankland has thus estimated the comparative value of foods as bases of muscular exertion, and he has made out a table of the weight and cost of various articles that would require to be consumed daily to enable a man to support life, the equivalent of which has been already reckoned as the muscular force in action which would raise a man of 10 stone 10,000 feet.

After the supply of sufficient albuminoid matters in the food to provide for the necessary renewal of the tissues, the best materials for the production of internal and external work are non-nitrogenous matters, such as oil, fat, sugar, starch, gum, &c. When the work is increased, not so much extra meat as vegetable food, or its dietetic equivalent, fat, is demanded.

In comparing the cost of a daily sufficiency of the various foods to produce the required force, we must not forget the inconveniences which many of them entail. These inconveniences must be added to the cost. For example, suppose a man to have been living upon potatoes only, just supporting life with 5 lb a day, and then to get work which enabled him and required him to take a double supply of non-nitrogenous food, he would act unwisely if he were to swallow it in the form of 12 lb of cabbage. He would be knocked up by the sheer labour of carrying 12 lb extra in a vessel so ill-adapted to sustain heavy loads as the stomach. A similar objection would lie against milk, or veal, or apples, however cheap accident might make them; and a more serious objection still would hold against nine bottles of ale, or seven of stout. On the other hand, the over-concentration of cheese, beef dripping, and lump sugar, makes them nauseous when in large quantity or monotonously persisted in, though when introduced as a variety they are appetizing and digestible. There is no saving in using that against which the stomach is set, or which the absorbents refuse to assimilate.

Reverting to the illustration of the gang of a hundred prisoners, and supposing it were requisite to put them on hard labour equivalent to half "Frankland's unit" of 10

stone raised 10,000 feet—such, for instance, as carrying up ladders, altogether $1\frac{1}{2}$ mile high, three tons of stone daily—calculation would show that to add this amount of labour to the outgoings caused by the functioning of physiological life, would involve the addition to their spare diet of at least 117 lb of bread, or of 58 lb of bread with 44 lb of lean meat and 63 lb of potatoes. The slightest imperfection or indigestion of any of this would cause a loss of bodily weight, and cases of illness would be culpably frequent. Were a draught of milk, or a cup of cocoa and sugar, or some oatmeal porridge and treacle, or even a little dripping or butter or bacon given, the danger would probably be averted.

The most conspicuous fault in the dietary of the working classes is want of variety. Many of the articles which combine ample nutritiousness with small cost are habitually neglected, because when used exclusively they are disagreeable and unwholesome. From never being eaten they become absolutely unknown. There are many sorts of cheap beans, vetches, and pease, unheard of except at gentlemen's tables, of which a complete meal may be made, or which may support the dish of meat; while beet-root, cresses, kail, carrots, and other plants easily grown are left unused.

Quantity of Food required.—The calculations of Dr Playfair "on the food of man in relation to his useful work" enable us by another route to arrive at an estimate of what amount of solid victuals is required by an adult living by bodily labour to preserve his health under various circumstances. The circumstances which chiefly affect the question can be classified thus:—(1) bare existence; (2) moderate exercise; (3) active work; and (4) hard work.

1. The first is calculated from the mean of sundry prison dietaries, of the convalescents' diet at hospitals, that of London needlewomen, and of that supplied during the Lancashire cotton-famine, as reported by Mr Simon. The result is that in a condition of low health, without activity, $2\frac{1}{2}$ ounces of nitrogenous food, 1 ounce of fat, 12 ounces of starch, and $\frac{1}{4}$ of an ounce of mineral matters a day are necessary. The amount of carbon in this is equal to 7.44 ounces. In other words, a man's life will be shortened or burdened by disease in the future, or he will die of gradual starvation, unless his provision for a week is equivalent to 3 lb of meat with 1 lb of fat on it, or with the same quantity of butter or lard, two quarter loaves of bread, and about an ounce of salt and other condiments. If he cannot get meat, he must supply its place with at least two extra quarter loaves, or about a stone and a half of potatoes, or between 5 and 6 lb of oatmeal,—unless he is, indeed, so fortunate as to be able to get skim milk, of which 5 pints a week will replace the meat.

A person reduced to bare existence diet can undertake no habitual toil, mental or bodily, under the penalty of breaking down.

"Bare existence" diet is that which requires to be estimated for administration to certain classes of the community who have a claim on their fellow-countrymen that their lives and health shall be preserved *in statu quo*, but nothing further. Such are prisoners, paupers, or the members of a temporarily famine-stricken community.

It would be obviously unjust to apply the same scale of quantity and quality to all persons under varying circumstances of constitution and outward surroundings; and to attempt to feed in the same way all these people for short or long periods, idle or employed, with light work or hard work, in hot or in cold weather, excited by hope or depressed by failure, involves an error of either excess or defect, or both at once. The dietaries recommended by

the Home Office for prisoners very properly take all these circumstances into consideration. They allot "bare existence" diet only to those sentenced for short terms without labour. And they recognize the fact that a man's health is not injured (perhaps sometimes it is improved) by a few days of such abstinence as would in the long run be deleterious to him. Under a sentence of seven days a prisoner gets daily 1 lb of bread, and a quart of gruel containing 4 oz. of oatmeal. For more than seven and under twenty-one days he has an extra $\frac{1}{2}$ lb of bread. For longer terms it is advised to add potatoes and meat.

The nutritive value of the first named diet is thus calculated by Dr Pavy (*Treatise on Food*, p. 415).—

Nitrogenous matter.. .. .	1 500 oz
Fat	450 "
Carbohydrates	10 712 "

of the second—

Nitrogenous matter.. .. .	2 448 oz
Fat	708 "
Carbohydrates.. .. .	14 792 "

In the convict establishments prisoners are all under long sentence, and are classified for dietetic purposes according to their occupation.

The sparest of all is called "punishment diet," and is administered for offences against the internal discipline of the prison. It is equivalent to corporeal chastisement, being designed to make the stomach a source of direct pain. It is limited to a period of three days, and fully answers its proposed end as a deterrent by causing the solar plexus to experience the greatest amount of distress it is capable of, for after the expiration of that period sensation becomes blunted. It consists of 1 lb of bread and as much water as the prisoner chooses to drink. This last-named concession is not an unimportant one; for it has been already remarked that a supply of fluid enables starvation, and by implication abstinence, to be longer borne. At the same time it probably postpones the anaesthesia, and therefore makes the intended suffering more real. "Punishment diet" contains, in Dr Pavy's estimate,—

Nitrogenous matter.. .. .	1 226 oz
Carbohydrates.. .. .	8 170 "
Fat	0 256 "
Mineral matter	0 368 "
Total of dry solids	10 050 "

This is about half of what an average man requires to sustain himself without work, and under its discipline he would probably lose 3 or 4 ounces of his weight daily till his bodily substance was reduced by six-tenths, at which period, according to Chossat's experiments, he would die.

"Penal diet" is that which is apportioned for more protracted punishment. It may be continued for three months. It consists of 20 oz of bread, 8 oz of oatmeal, 20 oz of milk, and 16 oz of potatoes daily. Its chemical constituents are as follows:—

Nitrogenous matter	3 784 oz
Carbohydrates	19 864 "
Fat	1 750 "
Mineral matter	0 972 "
Total of dry solids	56 200 "

Upon this diet a fair amount of work may be done. The combustion of the carbohydrates evolves sufficient force to raise a ton 4193 feet; and thus the effete muscular substance may be worn off by destructive assimilation, making place for new muscle derived from the nitrogenous matter of which a bare sufficiency, but yet probably a sufficiency, is supplied. A man of strong constitution is usually found at the end of it to be in good health and of normal weight;

¹ Lecture delivered at the Royal Institution, London, April 25, 1865.

tributed to physiology a precision rarely attainable in our dealings with social economy. Mr Joule of Manchester analyzed, about thirty years ago, the relation which the heat, used as a source of power in machinery, bore to the force of motion thus made active. He showed that raising the temperature of 1 lb of water 1° Fahr. was equivalent to raising 772 lb to the height of 1 foot; and conversely, that the fall of 772 lb might be so applied as to heat 1 lb of water 1° Fahr. Thus, the mechanical work represented in lifting 772 lb 1 foot, or 1 lb 772 feet, forms the "dynamic equivalent," the measure of the possible strength of 1° of temperature as marked by the thermometer in 1 lb of water. Physiologists seized eagerly on the opportunity which Joule's demonstration seemed to afford them of estimating in actual numerals the relation of living bodies to the work they have to do. So much earth raised on an embankment represents so much heat developed in the machinery, be it living or dead. The fully digested food, converted through several stages into gaseous, liquid, and solid excretory matters, produces by its chemical changes a definite amount of heat, of which a definite amount escapes and a definite amount is employed in working the involuntary machinery of the body, and the rest is available for conversion at will into voluntary muscular actions.

It may be reckoned that the daily expenditure of force in working the machinery of the body—in raising the diaphragm about 15 times and contracting the heart about 60 times a minute, in continuously rolling the wave of the intestinal canal, and in various other involuntary movements, without anything to be fairly called work,—it may be reckoned that the expenditure of force in doing this is equal to that which would raise a man of 10 stone 10,000 feet.

There are several reasons for believing that in assigning their physiological functions to the several sorts of food, nearly all the business of begetting force should be ascribed to the solid hydrocarbons, starch and oil, by their conversion into carbonic acid and water, just as there are good grounds for thinking that it is the conversion of the solid hydrocarbon of coal into the same substances which drives a locomotive. To the nitrogenous aliments seems allotted primarily the task of continuously replacing the wear and tear of the nitrogenous tissues, while any excess of them assists the starch and oil in keeping up the animal heat.

One of the most cogent of the reasons for this view is that the chief nitrogenous excretion, the urea, is not increased in amount in proportion to the work done, as shown by the experiments of Messrs Fink and Wiscelenus; whereas the excretion of carbonic acid in a decided manner follows the amount of muscular exertion. Now, it is very clear that if the supply of power to do work depended on the decomposition and renewal of the muscles by flesh food, the urea must be exactly proportioned to the exertion, which is not the case.

To give an example of the mode of working out a problem by this theory. Professor Frankland, in a series of experiments made in 1866 at the Royal Institution, and published in the *London Philosophical Magazine*, vol. xxxii. p. 182, ascertains with the "calorimeter" (which reckons the amount of heat evolved as a thermometer does its degree) the quantity of energy or force evolved under the form of heat during the oxidation of a given weight of alimentary substance. It has been explained that heat and mechanical work, being convertible into one another, bear a constant proportion to one another; so that a definite production of so much heat invariably represents the potentiality of so much motion, used or wasted according to circumstances. From the reading of the calorimeter therefore may be calculated how many extra pounds ought to

be raised a foot high by a man who has eaten an extra pound of the food in question; how many steps a foot high he ought to raise a weight of ten stone (say himself) before he has worked out the value of his victuals. Professor Frankland has thus estimated the comparative value of foods as bases of muscular exertion, and he has made out a table of the weight and cost of various articles that would require to be consumed daily to enable a man to support life, the equivalent of which has been already reckoned as the muscular force in action which would raise a man of 10 stone 10,000 feet.

Name of Food.	Weight in pounds required.	Price per Lb.		Cost.	
		s.	d.	s.	d.
Cheshire cheese. . . .	1.156	0	10	0	11½
Potatoes	5.668	0	1	0	5½
Apples	7.815	0	11	0	11½
Oatmeal	1.281	0	2½	0	3½
Flour	1.311	0	2½	0	3½
Peas	1.325	0	3½	0	4½
Ground rice	1.341	0	4	0	5½
Arrowroot	1.287	1	0	1	3½
Bread	2.345	0	2	0	4½
Lean beef	3.592	1	0	3	6½
Lean veal	4.000	1	0	4	3½
Lean ham (boiled) . . .	3.901	1	0	4	0
Mackerel	3.124	0	8	2	1
Whiting	6.769	1	4	5	4
White of egg	8.745	0	6	4	4½
Hard-boiled egg . . .	2.200	0	6½	1	2½
Isinglass	1.377	16	0	22	0½
Milk	8.021	0	2½	1	8
Carrots	9.055	0	1½	1	2½
Cabbage	12.020	0	1	1	0½
Cocoa-nibs	0.735	1	0	1	1½
Butter	0.693	1	0	1	0½
Beef fat	0.535	0	10	0	5½
Cod-liver oil	0.553	0	6	1	11½
Lump sugar	1.505	0	6	0	9
Commercial grape sugar	1.537	0	3½	0	5½
Bass's pale ale (bottled)	9.141 s.	0	10	7	6
Guinness's stout . . .	6½ bottles	0	10	5	7½

After the supply of sufficient albuminoid matters in the food to provide for the necessary renewal of the tissues, the best materials for the production of internal and external work are non-nitrogenous matters, such as oil, fat, sugar, starch, gum, &c. When the work is increased, not so much extra meat as vegetable food, or its dietetic equivalent, fat, is demanded.

In comparing the cost of a daily sufficiency of the various foods to produce the required force, we must not forget the inconveniences which many of them entail. These inconveniences must be added to the cost. For example, suppose a man to have been living upon potatoes only, just supporting life with 5 lb a day, and then to get work which enabled him and required him to take a double supply of non-nitrogenous food, he would act unwisely if he were to swallow it in the form of 12 lb of cabbage. He would be knocked up by the sheer labour of carrying 12 lb extra in a vessel so ill-adapted to sustain heavy loads as the stomach. A similar objection would lie against milk, or veal, or apples, however cheap accident might make them; and a more serious objection still would hold against nine bottles of ale, or seven of stout. On the other hand, the over-concentration of cheese, beef dripping, and lump sugar, makes them nauseous when in large quantity or monotonously persisted in, though when introduced as a variety they are appetizing and digestible. There is no saving in using that against which the stomach is set, or which the absorbents refuse to assimilate.

Reverting to the illustration of the gang of a hundred prisoners, and supposing it were requisite to put them on hard labour equivalent to half "Frankland's unit" of 10

stone raised 10,000 feet—such, for instance, as carrying up ladders, altogether $1\frac{1}{2}$ mile high, three tons of stone daily—calculation would show that to add this amount of labour to the outgoings caused by the functioning of physiological life, would involve the addition to their spare diet of at least 117 lb of bread, or of 58 lb of bread with 44 lb of lean meat and 63 lb of potatoes. The slightest imperfection or indigestion of any of this would cause a loss of bodily weight, and cases of illness would be culpably frequent. Were a draught of milk, or a cup of cocoa and sugar, or some oatmeal porridge and treacle, or even a little dripping or butter or bacon given, the danger would probably be averted.

The most conspicuous fault in the dietary of the working classes is want of variety. Many of the articles which combine ample nutritiousness with small cost are habitually neglected, because when used exclusively they are disagreeable and unwholesome. From never being eaten they become absolutely unknown. There are many sorts of cheap beans, vetches, and pease, unheard of except at gentlemen's tables, of which a complete meal may be made, or which may support the dish of meat, while beet-root, cresses, kail, carrots, and other plants easily grown are left unused.

Quantity of Food required—The calculations of Dr Playfair "on the food of man in relation to his useful work"¹ enable us by another route to arrive at an estimate of what amount of solid victuals is required by an adult living by bodily labour to preserve his health under various circumstances. The circumstances which chiefly affect the question can be classified thus.—(1) bare existence, (2) moderate exercise, (3) active work; and (4) hard work.

1. The first is calculated from the mean of sundry prison dietaries, of the convalescents' diet at hospitals, that of London needlewomen, and of that supplied during the Lancashire cotton-famine, as reported by Mr Simon. The result is that, in a condition of low health, without activity, $2\frac{1}{2}$ ounces of nitrogenous food, 1 ounce of fat, 12 ounces of starch, and $\frac{1}{2}$ of an ounce of mineral matters a day are necessary. The amount of carbon in this is equal to 7.44 ounces. In other words, a man's life will be shortened or burdened by disease in the future, or he will die of gradual starvation, unless his provision for a week is equivalent to 3 lb of meat with 1 lb of fat on it, or with the same quantity of butter or lard, two quartern loaves of bread, and about an ounce of salt and other condiments. If he cannot get meat, he must supply its place with at least two extra quartern loaves, or about a stone and a half of potatoes, or between 5 and 6 lb of oatmeal,—unless he is, indeed, so fortunate as to be able to get skim milk, of which 5 pints a week will replace the meat.

A person reduced to bare existence diet can undertake no habitual toil, mental or bodily, under the penalty of breaking down.

"Bare existence" diet is that which requires to be estimated for administration to certain classes of the community who have a claim on their fellow-countrymen that their lives and health shall be preserved *in statu quo*, but nothing further. Such are prisoners, paupers, or the members of a temporarily famine stricken community.

It would be obviously unjust to apply the same scale of quantity and quality to all persons under varying circumstances of constitution and outward surroundings; and to attempt to feed in the same way all these people for short or long periods, idle or employed, with light work or hard work, in hot or in cold weather, excited by hope or depressed by failure, involves an error of either excess or defect, or both at once. The dietaries recommended by

the Home Office for prisoners very properly take all these circumstances into consideration. They allot "bare existence" diet only to those sentenced for short terms without labour. And they recognize the fact that a man's health is not injured (perhaps sometimes it is improved) by a few days of such abstinence as would in the long run be deleterious to him. Under a sentence of seven days a prisoner gets daily 1 lb of bread, and a quart of gruel containing 4 oz. of oatmeal. For more than seven and under twenty-one days he has an extra $\frac{1}{2}$ lb of bread. For longer terms it is advised to add potatoes and meat.

The nutritive value of the first named diet is thus calculated by Dr Pavy (*Treatise on Food*, p. 415) —

Nitrogenous matter	1 800 oz.
Fat	480 "
Carbohydrates	10 712 "

of the second—

Nitrogenous matter.	2 448 oz.
Fat.	608 "
Carbohydrates..	14 792 "

In the convict establishments prisoners are all under long sentence, and are classified for dietetic purposes according to their occupation.

The sparsest of all is called "punishment diet," and is administered for offences against the internal discipline of the prison. It is equivalent to corporeal chastisement, being designed to make the stomach a source of direct pain. It is limited to a period of three days, and fully answers its proposed end as a deterrent by causing the solar plexus to experience the greatest amount of distress it is capable of; for after the expiration of that period sensation becomes blunted. It consists of 1 lb of bread and as much water as the prisoner chooses to drink. This last-named concession is not an unimportant one; for it has been already remarked that a supply of fluid enables starvation, and by implication abstinence, to be longer borne. At the same time it probably postpones the anaesthesia, and therefore makes the intended suffering more real. "Punishment diet" contains, in Dr Pavy's estimate,—

Nitrogenous matter.	1 296 oz.
Carbohydrates.	8 160 "
Fat.	0 256 "
Mineral matter ..	0 868 "

Total of dry solids 10 080 "

This is about half of what an average man requires to sustain himself without work, and under its discipline he would probably lose 3 or 4 ounces of his weight daily till his bodily substance was reduced by six-tenths, at which period, according to Chossat's experiments, he would die.

"Penal diet" is that which is apportioned for more protracted punishment. It may be continued for three months. It consists of 20 oz. of bread, 8 oz. of oatmeal, 20 oz. of milk, and 16 oz. of potatoes daily. Its chemical constituents are as follows :—

Nitrogenous matter .	3 784 oz.
Carbohydrates .	19 864 "
Fat .	1 580 "
Mineral matter .	0 972 "

Total of dry solids 26 200 "

Upon this diet a fair amount of work may be done. The combustion of the carbohydrates evolves sufficient force to raise a ton 4193 feet; and thus the effete muscular substance may be worn off by destructive assimilation, making place for new muscle derived from the nitrogenous matter of which a bare sufficiency, but yet probably a sufficiency, is supplied. A man of strong constitution is usually found at the end of it to be in good health and of normal weight;

¹ Lecture delivered at the Royal Institution, London, April 28, 1865.

yet he has never probably experienced the content which arises from a *luxus*-consumption of food. It is intended to deny him the normal pleasure of the accumulation of reserve-force in the gastric region. This pleasurable sensation under ordinary circumstances much promotes digestion, so that the whole of the ingesta are made the best use of; and therefore in "penal diet," as above quoted, it has been found expedient to introduce the slight excess to be noticed above what is needful to accomplish the required work in "foot-tons" (see before). The penalty of the regimen involves a certain degree of waste.

A close imitation of "penal diet" is that which the duty of a responsible Government demands should be served out during a temporary famine, that is, one calculated not to last above three months. It is more economical to introduce the elements of variety in the diet than to be too monotonous,—that is, to save in the daily issue and to be occasionally liberal, to feast from time to time as a break in the regular fast. The expense of the excess is more than replaced by the diminished habitual ration, and that powerful preservative of life, anticipation of pleasure, is brought into play. A reduction of the allowance below what experience has indicated as "bare existence diet," made during the famine in Madras in the beginning of 1877, was attended with disastrous results.

By dint of mixing and varying his diet and making it consist of very nutritious articles, such as bread, meat, yolk of eggs and soup, Signor Cornaro (see CORNARO) succeeded in reducing the quantity he daily consumed to as little as 12 oz. (Venetian). But then he made the solids go much further by taking 14 oz. of good wine. And the probability is that this gentleman had a peculiar constitution, for, in spite of his many readers, he has had no imitators of the experiment on their own persons.

2 The appropriate food of the second class may be fairly represented by the dietaries of European soldiers in time of peace. The English soldier on home service, according to Dr Parkes, receives from Government 5½ lb of meat and 7 lb of bread weekly, and buys additional bread, vegetables, milk, and groceries out of his pay. Such a diet is sufficient for anybody under ordinary circumstances of regular light occupation; but should extra demands be made upon mind or body, weight is lost, and if the demands continue to be made the health will suffer. Mr F. Buckland, surgeon in the Guards, remarks (*Soc of Arts Journal*, 1863, quoted by Dr Playfair) that though the sergeants in the Guards fatten upon their rations, the quantity is not enough for recruits during their drill.

The Prussian soldier during peace gets weekly from his canteen 11 lb 1 oz. of rye bread, and not quite 2½ lb of meat. This is obviously insufficient, but under the conscription system it is reckoned that he will be able to make up the deficiency out of his own private means, or obtain charitable contributions from his friends. Dr Hildesheim (*Die Normal-Diät*, Berlin, 1856, p. 60) states that asthenic diseases are very common in the army, which leads to the inference that the chance assistance on which the authorities lean is not trustworthy. As the legal ration in these two services does not profess to be a man's full food, it is needless to analyze it. In the French infantry of the line each man during peace gets weekly 15 lb of bread, 3½ lb of meat, 2½ lb of haricot beans or other vegetables, with salt and pepper, and 1½ oz. of brandy. This seems to be enough to support a man under light employment. Its analysis gives—

Water	179 83 oz.
Nitrogenous matter (or albuminates)	30 17 "
Fat	9 29 "
Carbohydrates (or starch)	126 84 "
Total of dry solids	166 30 "

An Austrian under the same circumstances receives 13 9lb of bread, ½ lb of flour, and 3 3 lb of meat. The alimentary contents are—

Water	129 50 oz.
Nitrogenous matter	27 40 "
Fat	8 23 "
Carbohydrates	119 45 "

Total of dry solids 155 08 .

The Russian conscript is allowed weekly¹—

Black bread	7 lb.
Meat	7 lb.
Kawass (beer)	7 7 quarts.
Sour cabbage	24½ gills, = 122½ oz.
Barley	24½ gills, = 122½ oz.
Salts	10½ oz.
Horse radish	28 grains
Pepper	28 grains
Vinegar	5½ gills, = 26½ oz.

The "moderate exercise" of brain and muscle combined in the above classes is fairly represented in the convict scale by "light labour" (such as oakum-picking), and by "industrial employment" (such as tailoring, cobbling, Roman mosaic and mat making, basket weaving, &c). The dietary for prisoners thus engaged is nearly identical, except that the artisans using their brains are supplied with about an ounce extra daily.

The "industrial employment diet" for a week is thus analyzed by Dr Pavy.—

Weekly Allowance.		Nitro- genous matter	Carbo- hydrates	Fat.	Mineral Matter	Total water- free matter.
	oz	oz	oz	oz	oz.	oz
Cocoa	3 500	0 560	1 540	1 295	0 105	3 500
Oatmeal	14 000	1 764	8 932	0 784	0 420	11 900
Milk	28 000	1 148	1 456	1 092	0 224	3 920
Molasses	7 000		5 390			5 390
Salt	3 500				3 500	3 500
Barley	1 000	0 063	0 743	0 024	0 020	0 850
Bread	148 000	11 958	75 480	2 368	3 404	93 240
Cheese	4 000	1 340		0 972	0 216	2 528
Flour	8 625	0 931	6 081	0 172	0 147	7 331
Meat (cooked, without bone or gravy)	16 000	4 416		2 472	0 472	7 360
Shins (made into soup)	8 000	1 688		0 320	2 072	4 080
Suet	1 500			1 244	0 030	1 274
Carrots	1 000	0 013	0 145	0 002	0 010	0 170
Onions	3 000	0 036	0 216		0 018	0 270
Turnips	1 000	0 012	0 072		0 006	0 090
Potatoes	96 000	2 016	21 120	0 192	0 672	24 000
Total water-free matter		25 975	121 175	10 937	11 316	169 405

This is probably a fair model for the most economical dietary on which an artisan or labourer on light work can thrive. It may be observed that the principle of variety is very conspicuous, and in private life it is possible to introduce still more variety by cookery (see COOKERY). In the English and Prussian armies the introduction of variety is left to be attained by forcing the soldier to purchase some portion of his food out of his own pocket; in the French scale it is managed by issuing spices and various vegetables, and trusting to the innate genius of the Gaulish warrior for cooking. The issue of an occasional glass of brandy on holidays makes an agreeable change and benefits digestion, but if wine could be obtained it would be better, and not extravagant. The Austrian bill of fare is sadly monotonous. The Russian ration may be noticed as particularly liberal of accessory and antiscorbutic food, from which civil as well as military dieticians might take a useful hint.

¹ Report of Sanitary Commission, 1858, p. 425, quoted by Dr Parkes.

Vinegar and other vegetable acids are too much neglected by our handicraftsmen and soldiers: The Carthaginians are stated by Aristotle to have used vinegar as a substitute for wine during their campaigns, and the recipes given by Cato for flavouring vinegar with fruits show that it was in use among the labouring population in Italy.

3. "Active" labourers are those who get through such an amount of work daily, exclusive of Sundays, as may be represented by a walk of 20 miles. In this class are soldiers during a campaign, letter carriers, and engineers employed on field work or as artisans. These habitually consume on the average about a fifth more nitrogenous food and twice as much fat as the last class, while the quantity of vegetable hydrocarbons is not augmented, except in the Royal Engineers.

The "hard labour diet" of convict prisons fairly represents what the authorities consider the minimum. It is the same as that already described as "industrial employment diet," with the following additions:—barley, 1 oz.; bread, 20 oz.; shins for soup, 8 oz.; carrots, 1 oz.; onions, $\frac{1}{2}$ oz.; turnips, 1 oz. It contains, however, 14 oz. less milk, and 1 oz. less "meat."

The nutritive value of the additions may be seen by Dr Pavy's alimentary analysis, which is as follows:—

Weekly Additions.		Nitro- genous materi.	Carbo- hydrates	Fat.	Mineral matter.	Total water-free matter.
Barley ..	1 000	0 063	0 743	0 024	0 020	0 850
Bread ..	20 000	1 620	10 250	0 320	0 460	12 650
Shins ..	8 000	1 638	..	0 320	2 072	4 080

The same food is given summer and winter, though the demand must be greater to provide for the extra quantity of heat required to be produced in cold weather. But then the amount of work is diminished at the latter season by $1\frac{1}{2}$ hours, which is equivalent to an augmentation of the diet. The additions are more judicious than those made by the classes above mentioned who partly furnish their own food, for bread and vegetables constitute a large portion of the convict ration, and the extra quantity of soup replaces the lost milk, without risk of the waste in cooking common when the uneducated deal with solid meat.

4. "Hard work" is that got through by English navvies, hard-worked weavers, and blacksmiths, &c which is more earnest and intense than the enforced "hard labour" of the convict. It is difficult to obtain accurate information, but it would appear from Dr Playfair's estimates that the customary addition to the diet is entirely in nitrogenous constituents. The higher their wages the more meat the men eat.

The neglect of vegetables by the last two classes is in a physiological point of view imprudent, and possibly may be a contributing cause of an inordinate thirst for alcohol which impoverishes and degrades many among them. To satisfy their instinctive craving for a hydrocarbon, they take one convenient indeed in some respects, but of

which any excess is unwholesome. The discovery already mentioned of the production of force from the assimilation of starch leads to a knowledge, opposed to old prejudices but supported by experience, that the raising of the energies to their full height of usefulness may be effected by vegetable food quite as well as by the more stimulating and more expensive animal nutriment, or by the more rapidly absorbed alcohol.

With regard to the tables quoted above in which ultimate analyses are used as data for dietetic rules, it must be noticed that their authors deprecate arguments being founded on any but the very broadest characters of the articles analyzed. Specimens, even when of the highest quality, differ strangely from one another. Season, soil, modes of culture, the variations of species, and many other little known influences come into play and prevent our taking the market names of eatables as representatives of a definite chemical constitution. And it may be added that ample scope should be allowed for the peculiarities of the individual and of his life-history. In the application of general rules some one must be trusted to relax or strain them when circumstances require, or failures of a fatal character may occasionally result, and more often a galling perversion of justice.

Estimates for the thrifty management of food-supply have usually reference to the feeding of others rather than to the calculation of a man's own dietary. Enough has been said on that point under the head of the influence of diet upon health, and if a person really wants to bring down the expense of feeding himself to the lowest point, he can readily rate himself under one of the classes enumerated above, and act accordingly. It may, however, be doubted whether it is wise to reduce the diet to the minimum which the work requires. The certain evils of an accidental deficiency or of a miscalculation are so serious that the danger outweighs the possible inconvenience of a slight excess. It were an unthrifty thrift indeed which imperilled vigour of mind and body to effect a pecuniary saving, for there is no investment so remunerative as high health. A man need not consider that he is wasteful when he spends money upon making his bill of fare palatable and provocative of indulgence to the extent of moderate superfluity. Pleasure and prudence here walk hand in hand.

(T. K. CH.)

DIETRICH, CHRISTIAN WILHELM ERNST (1712-1774), was born at Weimar, where he was brought up early to the profession of art by his father Johann George, then painter of miniatures to the court of the grand duke. Being sent to Dresden to perfect himself under the care of Alexander Thiele, he had the good fortune to finish in two hours, at the age of eighteen, a picture which attracted the attention of the king of Saxony. Augustus II. was so pleased with Dietrich's readiness of hand that he gave him means to study abroad, and visit in succession the chief cities of Italy and the Netherlands. There he learnt to copy and to imitate masters of the previous century with a versatility truly surprising. Winckelmann, to whom he had been recommended, did not hesitate to call him the Raphael of landscape. Yet in this branch of his practice he merely imitated Salvator Rosa, Ruess, and Everdingen. He was more successful in aping the style of Rembrandt, and numerous examples of this habit may be found in the galleries of St Petersburg, Vienna, and Dresden. At Dresden, indeed, there are pictures acknowledged to be his, bearing the fictitious dates of 1636 and 1638, and the name of Rembrandt. Among Dietrich's cleverest reproductions we may account that of Ostade's manner in the Itinerant Singers at the National Gallery. His skill in catching the character of the later masters of Holland is shown in candle-light scenes, such as the Squirrel and the

Peep-Show at St Petersburg, where we are easily reminded of Godfried Schalcken. Dietrich tried every branch of art except portraits, painting Italian and Dutch views alternately with Scripture scenes and still life. In 1741 he was appointed court painter to August III. at Dresden, with an annual salary of 400 thalers (£60), conditional on the production of four cabinet pictures a year. This condition, no doubt, accounts for the presence of 52 of the master's panels and canvases in one of the rooms at the Dresden museum. These pieces enable the spectator, if careless of more serious occupation, to study the numerous varieties of a changing style. It is needless, perhaps, to add that Dietrich, though popular and probably the busiest artist of his time, never produced anything of his own; and his imitations are necessarily inferior to the originals which he affected to copy. His best work is certainly that which he gave to engravings. A copious collection of these at the British Museum, produced on the general lines of earlier men, such as Ostade and Rembrandt, reveal both spirit and skill. Dietrich, after his return from the Peninsula, generally signed himself "Dietericij," and with this signature most of his extant pictures are inscribed. His death took place at Dresden, after he had successively filled the important appointments of director of the school of painting at the Meissen porcelain factory and professor of the Dresden academy of arts.

DIEZ, FRIEDRICH CHRISTIAN (1794-1876), the founder of Romance philology, was born at Giessen, in Hesse-Darmstadt, March 15, 1794, and died at Bonn, May 29, 1876. He was educated first at the gymnasium and then at the university of his native town. There he studied classics under Welcker, who had just returned from a two years' residence in Italy to fill the chair of archaeology and Greek literature. It was Welcker who kindled in him a love of Italian poetry, and thus gave the first bent to his genius. In 1813 he joined the Hesse corps as a volunteer and served in the French campaign. Next year he returned to his books, and this short taste of military service was the only break in a long and uneventful life of literary labours. By his parents' desire he applied himself for a short time to law, but a visit to Goethe in 1818 gave a new direction to his studies, and determined his future career. Goethe had been reading Raynouard's *Selections from the Romance Poets*, and advised the young scholar to explore the rich mine of Provençal literature which the French savant had opened up. This advice was eagerly followed, and henceforth Diez devoted himself to Romance literature. After supporting himself for some years by private teaching, he removed in 1822 to Bonn, where he held the position of privat-docent, which is the lowest grade of the German professoriate. In 1823 he published his first work, *An Introduction to Romance Poetry*; in the following year appeared *The Poetry of the Troubadours*, and in 1829 *The Lives and Works of the Troubadours*. In 1830 he was called to the chair of modern literature. The rest of his life was mainly occupied with the composition of the two great works on which his fame rests, the *Grammar of the Romance Languages*, 1836-1844, and the *Lexicon of the Romance Languages—Italian, Spanish, and French*, 1853.

In these two works Diez has done for the Romance group of languages what Jacob Grimm has for the Teutonic family. In both cases much remains to be accomplished, many words and forms are not yet accounted for, some errors have already been pointed out, but all future philologists must build on the foundations which these two men have laid. "Nothing," says Max Müller, "can be a better preparation for the study of the comparative grammar of the ancient Aryan language than a careful perusal of the comparative grammar of the six Romance languages by Professor Diez."

In order to appreciate the importance of Diez's work it is necessary to take a rapid glance at the history of philology in France. The earliest philologists, such as Perion and Henri Estienne, sought to discover the origin of French in Greek and even in Hebrew. For more than a century Ménage's *Etymological Dictionary* held the field without a rival. Considering the time at which it was written (1650), it was a meritorious work, but philology was then in the empirical stage, and many of Ménage's derivations (such as that of "rat" from the Latin "mus," or of "haricot" from "faba") have since become by-words among philologists. A great advance was made by Raynouard, who by his critical editions of the works of the Troubadours, published in the first years of the present century, laid the foundations on which Diez afterwards built. The difference between Diez's method and that of his predecessors is well stated by him in the preface to his dictionary. In sum it is the difference between science and guess-work. The scientific method is to follow implicitly the discovered principles and rules of phonology, and not to swerve a foot's breadth from them unless plain, actual exceptions shall justify it; to follow the genius of the language, and by cross-questioning to elicit its secrets; to gauge each letter and estimate the value which attaches to it in each position; and lastly to possess the true philosophic spirit which is prepared to welcome any new fact, though it may modify or upset the most cherished theory.

Such is the historical method which Diez pursues in his grammar and dictionary. To collect and arrange facts is, as he tells us, the sole secret of his success, and he adds in other words the famous apophthegm of Newton, "hypotheses non fingo."

The introduction to the grammar consists of two parts:—the first discusses the Latin, Greek, and Teutonic elements common to the Romance languages; the second treats of the six dialects separately, their origin, and the elements peculiar to each. The grammar itself is divided into four books, on phonology, on flexion, on the formation of words by composition and derivation, and on syntax.

His dictionary is divided into two parts. The first contains words common to two at least of the three principal groups of Romance,—Italian, Spanish and Portuguese, and Provençal and French. The Italian, as nearest the original, is placed at the head of each article. The second part treats of words peculiar to one group. There is no separate glossary of Wallachian.

Of the introduction to the grammar there is an excellent translation into French by Gaston Paris, a pupil of Diez, and an English translation by C. B. Cayler. The dictionary has been published in a remodelled form for English readers by T. C. Donkin. A second edition, enlarged and corrected, appeared in 1861, and a third edition was begun in 1869.

DIFFERENTIAL CALCULUS. See INFINITESIMAL CALCULUS.

DIFFUSION. Some liquids, such as mercury and water, when placed in contact with each other do not mix at all, but the surface of separation remains distinct, and exhibits the phenomena described under CAPILLARY ACTION. Other pairs of liquids, such as chloroform and water, mix, but only in certain proportions. The chloroform takes up a little water, and the water a little chloroform; but the two mixed liquids will not mix with each other, but remain in contact separated by a surface showing capillary phenomena. The two liquids are then in a state of equilibrium with each other. The conditions of the equilibrium of heterogeneous substances have been investigated by Professor J. Willard Gibbs in a series of papers published in the *Transactions of the Connecticut Academy of Arts and Sciences*, vol. iii. part i. p. 108. Other pairs of liquids, and all gases, mix in all proportions.

When two fluids are capable of being mixed, they cannot remain in equilibrium with each other; if they are placed in contact with each other the process of mixture begins of itself, and goes on till the state of equilibrium is attained, which, in the case of fluids which mix in all proportions, is a state of uniform mixture.

This process of mixture is called diffusion. It may be easily observed by taking a glass jar half full of water and pouring a strong solution of a coloured salt, such as sulphate of copper, through a long-stemmed funnel, so as to occupy the lower part of the jar. If the jar is not disturbed we may trace the process of diffusion for weeks, months, or years, by the gradual rise of the colour into the upper part of the jar, and the weakening of the colour in the lower part.

This, however, is not a method capable of giving accurate measurements of the composition of the liquid at different depths in the vessel. For more exact determinations we may draw off a portion from a given stratum of the mixed liquid, and determine its composition either by chemical methods or by its specific gravity, or any other property from which its composition may be deduced.

But as the act of removing a portion of the fluid interferes with the process of diffusion, it is desirable to be able to ascertain the composition of any stratum of the mixture without removing it from the vessel. For this purpose Sir W. Thomson places in the jar a number of glass beads of different densities, which indicate the densities of the strata in which they are observed to float. The principal objection to this method is, that if the liquids contain air or any other gas, bubbles are apt to form on the glass beads, so as to make them float in a stratum of less density than that marked on them.

M. Voigt has observed the diffusion of cane-sugar in water by passing a ray of plane-polarized light horizontally through the vessel, and determining the angle through which the plane of polarization is turned by the solution of sugar. This method is of course applicable only to those substances which cause rotation of the plane of polarized light.

Another method is to place the diffusing liquids in a hollow glass prism, with its refracting edge vertical, and to determine the deviation of a ray of light passing through the prism at different depths. The ray is bent downwards on account of the variable density of the mixture, as well as towards the thicker part of the prism; but by making it pass as near the edge of the prism as possible, the vertical component of the refraction may be made very small; and by placing the prism within a vessel of water having parallel sides of glass, we can get rid of the constant part of the deviation, and are able to use a prism of large angle, so as to increase the part due to the diffusing substance. At the same time we can more easily control and register the temperature.

The laws of diffusion were first investigated by Graham. The diffusion of gases has recently been observed with great accuracy by Loschmidt, and that of liquids by Fick and by Voigt.

Diffusion as a molecular motion.—If we observe the process of diffusion with our most powerful microscopes, we cannot follow the motion of any individual portions of the fluids. We cannot point out one place in which the lower fluid is ascending, and another in which the upper fluid is descending. There are no currents visible to us, and the motion of the material substances goes on as imperceptibly as the conduction of heat or of electricity. Hence the motion which constitutes diffusion must be distinguished from those motions of fluids which we can trace by means of floating motes. It may be described as a motion of the fluids, not *in mass*, but by *molecules*.

When we reason upon the hypothesis that a fluid is a continuous homogeneous substance, it is comparatively easy to define its density and velocity; but when we admit that it may consist of molecules of different kinds, we must revise our definitions. We therefore define these quantities by considering that part of the medium which at a given instant is within a certain small region surrounding a given point. This region must be so small that the properties of the medium as a whole are sensibly the same throughout the region, and yet it must be so large as to include a large number of molecules. We then define the density of the medium at the given point as the mass of the medium within this region divided by its volume, and the velocity of the medium as the momentum of this portion of the medium divided by its mass.

If we consider the motion of the medium relative to an imaginary surface supposed to exist within the region occupied by the medium, and if we define the flow of the medium through the surface as the mass of the medium which in unit of time passes through unit of area of the surface, then it follows from the above definitions that the velocity of the medium resolved in the direction of the normal to the surface is equal to the flow divided by the density. If we suppose the surface itself to move with the same velocity as the fluid, and in the same direction, there will be no flow through it.

Having thus defined the density, velocity, and flow of the medium as a whole, or, as it is sometimes expressed, "in mass," we may now consider one of the fluids which constitute the medium, and define its density, velocity, and flow in the same way. The velocity of this fluid may be different from that of the medium in mass, and its velocity relative to that of the medium is the velocity of diffusion which we have to study.

Diffusion of Gases according to the Kinetic Theory

So many of the phenomena of gases are found to be explained in a consistent manner by the kinetic theory of gases, that we may describe with considerable probability of correctness the kind of motion which constitutes diffusion in gases. We shall therefore consider gaseous diffusion in the light of the kinetic theory before we consider diffusion in liquids.

A gas, according to the kinetic theory, is a collection of particles or molecules which are in rapid motion, and which, when they encounter each other, behave pretty much as elastic bodies, such as billiard balls, would do if no energy were lost in their collisions. Each molecule travels but a very small distance between one encounter and another, so that it is every now and then altering its velocity both in direction and magnitude, and that in an exceedingly irregular manner.

The result is that the velocity of any molecule may be considered as compounded of two velocities, one of which, called the velocity of the medium, is the same for all the molecules, while the other, called the velocity of agitation, is irregular both in magnitude and in direction, though the average magnitude of the velocity may be calculated, and any one direction is just as likely as any other.

The result of this motion is, that if in any part of the medium the molecules are more numerous than in a neighboring region, more molecules will pass from the first region to the second than in the reverse direction, and for this reason the density of the gas will tend to become equal in all parts of the vessel containing it, except in so far as the molecules may be crowded towards one direction by the action of an external force such as gravity. Since the motion of the molecules is very swift, the process of equalization of density in a gas is a very

rapid one, its velocity of propagation through the gas being that of sound.

Let us now consider two gases in the same vessel, the proportion of the gases being different in different parts of the vessel, but the pressure being everywhere the same. The agitation of the molecules will still cause more molecules of the first gas to pass from places where that gas is dense to places where it is rare than in the opposite direction, but since the second gas is dense where the first one is rare, its molecules will be for the most part travelling in the opposite direction. Hence the molecules of the two gases will encounter each other, and every encounter will act as a check to the process of equalization of the density of each gas throughout the mixture.

The interdiffusion of two gases in a vessel is therefore a much slower process than that by which the density of a single gas becomes equalized, though it appears from the theory that the final result is the same, and that each gas is distributed through the vessel in precisely the same way as if no other gas had been present, and this even when we take into account the effect of gravity.

If we apply the ordinary language about fluids to a single gas of the mixture, we may distinguish the forces which act on an element of volume as follows—

- 1st Any external force, such as gravity or electricity
- 2d The difference of the pressure of the particular gas on opposite sides of the element of volume [The pressure due to other gases is to be considered of no account]
- 3d. The resistance arising from the percolation of the gas through the other gases which are moving with different velocity

The resistance due to encounters with the molecules of any other gas is proportional to the velocity of the first gas relative to the second, to the product of their densities, and to a coefficient which depends on the nature of the gases and on the temperature. The equations of motion of one gas of a mixture are therefore of the form

$$\rho_1 \frac{\delta_1 u_1}{\delta t} + \frac{dp_1}{dx} - X_1 \rho_1 + C_{12} \rho_1 \rho_2 (u_1 - u_2) + C_{13} \rho_1 \rho_3 (u_1 - u_3) + \&c. = 0,$$

where the symbol of operation $\frac{\delta_1}{\delta t}$ prefixed to any quantity denotes the time-variation of that quantity at a point which moves along with that medium which is distinguished by the suffix (1), or more explicitly

$$\frac{\delta_1}{\delta t} = \frac{d}{dt} + u_1 \frac{d}{dx} + v_1 \frac{d}{dy} + w_1 \frac{d}{dz}.$$

In the state of ultimate equilibrium $u_1 = u_2 = \&c. = 0$, and the equation is reduced to

$$\frac{dp_1}{dx} - X_1 \rho_1 = 0,$$

which is the ordinary form of the equations of equilibrium of a single fluid. Hence, when the process of diffusion is complete, the density of each gas at any point of the vessel is the same as if no other gas were present.

If V_1 is the potential of the force which acts on the gas, and if in the equation $p_1 = k_1 \rho_1$, k_1 is constant, as it is when the temperature is uniform, then the equation of equilibrium becomes

$$k_1 \frac{d\rho_1}{dx} + \frac{dV_1}{dx} \rho_1 = 0,$$

the solution of which is

$$\rho_1 = A_1 e^{-\frac{V_1}{k_1}}.$$

Hence if, as in the case of gravity, V is the same for all gases, but k is different for different gases, the composition of the mixture will be different in different parts of the vessel, the proportion of the heavier gases, for which k is smaller, being greater at the bottom of the vessel than at the top. It would be difficult, however, to obtain experimental evidence of this difference of composition except in a vessel more than 100 metres high, and it would be necessary to keep the vessel free from inequalities of temperature for more than a year, in order to allow the process of diffusion to advance to a state even half way towards that of ultimate equilibrium. The experiment might, however, be made in a few minutes by placing a tube, say 10 centimetres long, on a whirling apparatus, so that one end shall be close to the axis, while the other is moving at the rate, say, of 50 metres per second. Thus if equal volumes of hydrogen and carbonic acid were used, the proportion

of hydrogen to carbonic acid would be about $\frac{1}{17}$ greater at the end of the tube nearest the axis. The experimental verification of the result is important, as it establishes a method of effecting the partial separation of gases without the selective action of chemical agents.

Let us next consider the case of diffusion in a vertical cylinder. Let m_1 be the mass of the first gas in a column of unit area extending from the bottom of the vessel to the height x , and let v_1 be the volume which this mass would occupy at unit pressure, then

$$\begin{aligned} k_1 m_1 &= v_1, \\ \rho_1 &= \frac{dm_1}{dx}, \quad \rho_1 u_1 = -\frac{dm_1}{dt}, \\ p_1 &= \frac{dv_1}{dx}, \quad p_1 u_1 = -\frac{dv_1}{dt}, \end{aligned}$$

and the equation of motion becomes

$$\begin{aligned} \frac{1}{k_1 \frac{dv_1}{dx}} \left\{ \frac{d^2 v_1}{dx^2} \frac{dv_1}{dt} - \frac{dv_1}{dx} \frac{d^2 v_1}{dt^2} \right\} + \frac{d^2 v_1}{dx^2} - \frac{X}{k_1} \frac{dv_1}{dx} \\ + \frac{C_{12}}{k_1 k_2} \left\{ \frac{dv_2}{dt} \frac{dv_1}{dx} - \frac{dv_1}{dt} \frac{dv_2}{dx} \right\} + \&c. = 0. \end{aligned}$$

If we add the corresponding equations together for all the gases, we find that the terms in C_{12} destroy each other, and that if the medium is not affected with sensible currents the first term of each equation may be neglected. In ordinary experiments we may also neglect the effect of gravity, so that we get

$$\frac{d^2}{dx^2} (v_1 + v_2) = 0,$$

or

$$v_1 + v_2 = px,$$

where p is the uniform pressure of the mixed medium. Hence

$$\frac{dv_1}{dt} = -\frac{dv_1}{dx} \quad \text{and} \quad \frac{dv_2}{dx} = p - \frac{dv_1}{dx},$$

and the equation becomes

$$\frac{d^2 v_1}{dx^2} = \frac{C_{12}}{k_1 k_2} p \frac{dv_1}{dt},$$

an equation, the form of which is identical with the well known equation for the conduction of heat. We may write it

$$\frac{dv_1}{dt} = D \frac{d^2 v_1}{dx^2}.$$

D is called the coefficient of diffusion. It is equal to

$$\frac{k_1 k_2}{C_{12} p}$$

It therefore varies inversely as the total pressure of the medium, and if the coefficient of resistance, C_{12} , is independent of the temperature, it varies directly as the product $k_1 k_2$, i.e., as the square of the absolute temperature. It is probable, however, that the effect of temperature is not so great as this would make it.

In liquids D probably depends on the proportion of the ingredients of the mixed medium as well as on the temperature. The dimensions of D are $L^2 T^{-1}$, where L is the unit of length and T the unit of time.

The values of the coefficients of diffusion of several pairs of gases have been determined by Loschmidt.¹ They are referred in the following table to the centimetre and the second as units, for the temperature 0°C and the pressure of 76 centimetres of mercury.

Diffusion in Liquids.

The nature of the motion of the molecules in liquids is less understood than in gases, but it is easy to see that if there is any irregular displacement among the molecules in a mixed liquid, it must, on the whole, tend to cause each component to pass from places where it forms a large proportion of the mixture to places where it is less abundant. It is also manifest that any relative motion of two constituents of the mixture will be opposed by a resistance arising from

¹ Imperial Academy of Vienna, 10th March 1870.

the encounters between the molecules of these components. The value of this resistance, however, depends, in liquids, on more complicated conditions than in gases, and for the present we must regard it as a function of all the physical properties of the mixture at the given place, that is to say, its temperature and pressure, and the proportions of the different components of the mixture.

The coefficient of interdiffusion of two liquids must therefore be considered as depending on all the physical properties of the mixture according to laws which can be ascertained only by experiment.

Thus Fick has determined the coefficient of diffusion for common salt in water to be 0.0000116, and Voit has found that of cane-sugar to be 0.00000365

It appears from these numbers that in a vessel of the same size the process of diffusion of liquids requires a greater number of days to reach a given stage than the process of diffusion of gases in the same vessel requires seconds.

When we wish to mix two liquids, it is not sufficient to place them in the same vessel, for if the vessel is, say, a metre in depth, the lighter liquid will lie above the denser, and it will be many years before the mixture becomes even sensibly uniform. We therefore stir the two liquids together, that is to say, we move a solid body through the vessel, first one way, then another, so as to make the liquid contents eddy about in as complicated a manner as possible. The effect of this is that the two liquids, which originally formed two thick horizontal layers, one above the other, are now disposed in thin and excessively convoluted strata, which, if they could be spread out, would cover an immense area. The effect of the stirring is thus to increase the area over which the process of diffusion can go on, and to diminish the distance between the diffusing liquids; and since the time required for diffusion varies as the square of the thickness of the layers, it is evident that by a moderate amount of stirring the process of mixture which would otherwise require years may be completed in a few seconds. That the process is not instantaneous is easily ascertained by observing that for some time after the stirring the mixture appears full of streaks, which cause it to lose its transparency. This arises from the different indices of refraction of different portions of the mixture which have been brought near each other by stirring. The surfaces of separation are so drawn out and convoluted, that the whole mass has a woolly appearance, for no ray of light can pass through it without being turned many times out of its path.

Graham observed that the diffusion both of liquids and gases takes place through porous solid bodies, such as plugs of plaster of Paris or plates of pressed plumbago, at a rate not very much less than when no such body is interposed, and thus even when the solid partition is amply sufficient to check all ordinary currents, and even to sustain a considerable difference of pressure on its opposite sides.

But there is another class of cases in which a liquid or a gas can pass through a diaphragm, which is not, in the ordinary sense, porous. For instance, when carbonic acid gas is confined in a soap bubble it rapidly escapes. The gas is absorbed at the inner surface of the bubble, and forms a solution of carbonic acid in water. This solution diffuses from the inner surface of the bubble, where it is strongest, to the outer surface, where it is in contact with air, and the carbonic acid evaporates and diffuses out into the atmosphere. It is also found that hydrogen and other gases can pass through a layer of caoutchouc. Graham showed that it is not through pores, in the ordinary sense, that the motion takes place, for the ratios are determined by the chemical relations between the gases and the caoutchouc, or the liquid film.

According to Graham's theory, the caoutchouc is a colloid substance,—that is, one which is capable of combining, in a temporary and very loose manner, with indeterminate proportions of certain other substances, just as glue will form a jelly with various proportions of water. Another class of substances, which Graham called crystalloid, are distinguished from these by being always of definite composition, and not admitting of these temporary associations. When a colloid body has in different parts of its mass different proportions of water, alcohol, or solutions of crystalloid bodies, diffusion takes place through the colloid body, though no part of it can be shown to be in the liquid state.

On the other hand, a solution of a colloid substance is almost incapable of diffusion through a porous solid, or another colloid body. Thus, if a solution of gum and salt in water is placed in contact with a solid jelly of gelatine and alcohol, alcohol will be diffused into the gum, and salt and water will be diffused into the gelatine, but the gum and the gelatine will not diffuse into each other.

There are certain metals whose relations to certain gases Graham explained by this theory. For instance, hydrogen can be made to pass through iron and palladium at a high temperature, and carbonic oxide can be made to pass through iron. The gases form colloidal unions with the metals, and are diffused through them as water is diffused through a jelly. Root has lately found that hydrogen can pass through platinum, even at ordinary temperatures.

By taking advantage of the different velocities with which different liquids and gases pass through parchment-paper and other solid bodies, Graham was enabled to effect many remarkable analyses. He called this method the method of Dialysis.

Diffusion and Evaporation, Condensation, Solution, and Absorption.

The rate of evaporation of liquids is determined principally by the rate of diffusion of the vapour through the air or other gas which lies above the liquid. Indeed, the coefficient of diffusion of the vapour of a liquid through air can be determined in a rough but easy manner by placing a little of the liquid in a test tube, and observing the rate at which its weight diminishes by evaporation day by day. For at the surface of the liquid the density of the vapour is that corresponding to the temperature, whereas at the mouth of the test tube the air is nearly pure. Hence, if p be the pressure of the vapour corresponding to the temperature, and $p = kp$, and if m be the mass evaporated in time t , and diffused into the air through a distance h ,¹ then

$$D = \frac{hkm}{pt}.$$

This method is not, of course, applicable to vapours which are rarer than the superincumbent gas.

The solution of a salt in a liquid goes on in the same way, and so does the absorption of a gas by a liquid.

These processes are all accelerated by currents, for the reason already explained.

The processes of evaporation and condensation go on much more rapidly when no air or other non-condensable gas is present. Hence the importance of the air-pump in the steam engine.

Relation between Diffusion of Matter and Diffusion of Heat.

The same motion of agitation of the molecules of gases which causes two gases to diffuse through each other also

¹ h should be taken equal to the height of the tube above the surface of the liquid, together with about $\frac{1}{4}$ of the diameter of the tube.—See Clerk Maxwell's *Electricity*, Art. 309

causes two portions of the same gas to diffuse through each other, although we cannot observe this kind of diffusion, because we cannot distinguish the molecules of one portion from those of the other when they are once mixed. If, however, the molecules of one portion have any property whereby they can be distinguished from those of the other, then that property will be communicated from one part of the medium to an adjoining part, and that either by convection—that is by the molecules themselves passing out of one part into the other, carrying the property with them—or by transmission—that is by the property being communicated from one molecule to another during their encounters. The chemical properties by which different substances are recognized are inseparable from their molecules, so that the diffusion of such properties can take place only by the transference of the molecules themselves, but the momentum of a molecule in any given direction and its energy are also properties which may be different in different molecules, but which may be communicated from one molecule to another. Hence the diffusion of momentum and that of energy through the medium can take place in two different ways, whereas the diffusion of matter can take place only in one of these ways.

In gases the great majority of the particles, at any instant, are describing free paths, and it is therefore possible to show that there is a simple numerical relation between the coefficients of the three kinds of diffusion,—the diffusion of matter, the lateral diffusion of velocity (which is the phenomenon known as the internal friction or viscosity of fluids), and the diffusion of energy (which is called the conduction of heat). But in liquids the majority of the molecules are engaged at close quarters with one or more other molecules, so that the transmission of momentum and of energy takes place in a far greater degree by communication from one molecule to another, than by convection by the molecules themselves. Hence the ratios of the coefficient of diffusion to those of viscosity and thermal conductivity are much smaller in liquids than in gases.

Theory of the Wet Bulb Thermometer.

The temperature indicated by the wet bulb thermometer is determined in great part by the relation between the coefficients of diffusion and thermal conductivity. As the water evaporates from the wet bulb heat must be supplied to it by convection, conduction, or radiation. This supply of heat will not be sufficient to maintain the temperature constant till the temperature of the wet bulb has sunk so far below that of the surrounding air and other bodies that the flow of heat due to the difference of temperature is equal to the latent heat of the vapour which leaves the bulb.

The use of the wet bulb thermometer as a means of estimating the humidity of the atmosphere was employed by Hutton¹ and Leshe,² but the formula by which the dew-point is commonly deduced from the readings of the wet and dry thermometers was first given by Dr Apjohn.³

Dr Apjohn assumes that, when the temperature of the wet bulb is stationary, the heat required to convert the water into vapour is given out by portions of the surrounding air in cooling from the temperature of the atmosphere to that of the wet bulb, and that the air thus cooled becomes saturated with the vapour which it receives from the bulb.

Let m be the mass of a portion of air at a distance from the wet bulb, θ its temperature, p_0 the pressure due to the aqueous vapour in it, and P the whole pressure.

If σ is the specific gravity of aqueous vapour (referred to air), then the mass of water in this portion of air is $\frac{p}{P} \sigma m$.

Let this portion of air communicate with the wet bulb till its temperature sinks to θ_1 , that of the wet bulb, and the pressure of the aqueous vapour in it rises to p_1 , that corresponding to the temperature θ_1 .

The quantity of vapour which has been communicated to the air is

$$(p_1 - p_0) \frac{\sigma m}{P},$$

and if L is the latent heat of vapour at the temperature θ_1 , the quantity of heat required to produce this vapour is

$$(p_1 - p_0) \frac{\sigma m}{P} L$$

According to Apjohn's theory, this heat is supplied by the mixed air and vapour in cooling from θ to θ_1 .

If S is the specific heat of the air (which will not be sensibly different from that of dry air), this quantity of heat is

$$(\theta - \theta_1) m S.$$

Equating the two values we obtain

$$p_0 = p_1 - \frac{PS}{L\sigma} (\theta - \theta_1)$$

Here p_0 is the pressure of the vapour in the atmosphere. The temperature—for which this is the maximum pressure—is the dew-point, and p_1 is the maximum pressure corresponding to the temperature θ_1 of the wet bulb. Hence this formula, combined with tables of the pressure of aqueous vapour, enables us to find the dew-point from observations of the wet and dry bulb thermometers.

We may call this the convection theory of the wet bulb, because we consider the temperature and humidity of a portion of air brought from a distance to be affected directly by the wet bulb without communication either of heat or of vapour with other portions of air.

Dr Everett has pointed out as a defect in this theory, that it does not explain how the air can either sink in temperature or increase in humidity unless it comes into absolute contact with the wet bulb. Let us, therefore, consider what we may call the conduction and diffusion theory in calm air, taking into account the effects of radiation.

The steady conduction of heat is determined by the conditions—

$$\begin{aligned} \theta &= \theta_0 \text{ at a great distance from the bulb,} \\ \theta &= \theta_1 \text{ at the surface of the bulb,} \\ \nabla^2 \theta &= 0 \text{ at any point of the medium.} \end{aligned}$$

The steady diffusion of vapour is determined by the conditions—

$$\begin{aligned} p &= p_0 \text{ at a great distance from the bulb,} \\ p &= p_1 \text{ at the surface of the bulb,} \\ \nabla^2 p &= 0 \text{ at any point of the medium.} \end{aligned}$$

Now, if the bulb had been an electrified conductor, the conditions with respect to the potential would have been

$$\begin{aligned} V &= 0 \text{ at a great distance,} \\ V &= V_1 \text{ at the surface,} \\ \nabla^2 V &= 0 \text{ at any point outside the bulb} \end{aligned}$$

Hence the solution of the electrical problem leads to that of the other two. For if V is the potential at any point,

$$\theta = \theta_0 + (\theta_1 - \theta_0) \frac{V}{V_1} \quad p = p_0 + (p_1 - p_0) \frac{V}{V_1}.$$

If E is the electric charge of the conductor,

$$4\pi E = - \iint \frac{dV}{dv} dS,$$

where the double integral is extended over the surface of the bulb, and dv is an element of a normal to the surface.

If H is the flow of heat in unit of time from the bulb,

$$H = -K \iint \frac{d\theta}{dv} dS,$$

and if Q is the flow of aqueous vapour from the bulb,

$$Q = -\frac{D}{k} \iint \frac{dp}{dv} dS,$$

where k is the ratio of the pressure of aqueous vapour to its density.

If C is the electrical capacity of the bulb, $E = CV_1$,

$$H = 4\pi CK(\theta_1 - \theta_0), \quad Q = 4\pi C \frac{D}{k} (p_1 - p_0).$$

The heat which leaves the bulb by radiation to external objects at temperature θ_0 may be written

$$h = AR(\theta_1 - \theta_0),$$

where A is the surface of the bulb and R the coefficient of radiation of unit of surface.

When the temperature becomes constant

$$LQ + H + h = 0,$$

$$p_0 = -p_1 \left\{ \frac{K}{L\sigma} + \frac{AR}{4\pi C p_1 SD} \right\} (\theta_0 - \theta_1).$$

This formula gives the result of the theory of diffusion, conduc-

¹ Playfair's "Life of Hutton," *Edinburgh Transactions*, vol. v. p. 67, note.

³ *Trans. Royal Irish Academy*, 1834.

tion, and radiation in a still atmosphere. It differs from the formula of the convection theory only by the factor in the last term.

The first part of this factor $\frac{K}{D}$ is certainly less than unity, and probably about .77

If the bulb is spherical and of radius r , $A = 4\pi r^2$ and $C = r$, so that the second part is $\frac{Kr}{\rho SD}$.

Hence, the larger the wet bulb, the greater will be the ratio of the effect of radiation to that of conduction. If, on the other hand, the air is in motion, this will increase both conduction and diffusion, so as to increase the ratio of the first part to the second. By comparing actual observations of the dew-point with Apjohn's formula, it has been found that the factor should be somewhat greater than unity. According to our theory it ought to be greater if the bulb is larger, and smaller if there is much wind.

Relation between Diffusion and Electrolytic Conduction.

Electrolysis (see separate article) is a molecular movement of the constituents of a compound liquid in which, under the action of electromotive force, one of the components travels in the positive and the other in the negative direction, the flow of each component, when reckoned in electrochemical equivalents, being in all cases numerically equal to the flow of electricity.

Electrolysis resembles diffusion in being a molecular movement of two currents in opposite directions through the same liquid; but since the liquid is of the same composition throughout, we cannot ascribe the currents to the molecular agitation of a medium whose composition varies from one part to another as in ordinary diffusion, but we must ascribe it to the action of the electromotive force on particles having definite charges of electricity.

The force, therefore, urging an electro-chemical equivalent of either component, or ion, as it is called, in a given direction is numerically equal to the electromotive force at a given point of the electrolyte, and is therefore comparable with any ordinary force. The resistance which prevents the current from rising above a certain value is that arising from the encounters of the molecules of the ion with other molecules as they struggle forward through the liquid, and this depends on their relative velocity, and also on the nature of the ion, and of the liquid through which it has to flow.

The average velocity of the ions will therefore increase, till the resistance they meet with is equal to the force which urges them forward, and they will thus acquire a definite velocity proportional to the electric force at the point, but depending also on the nature of the liquid.

If the resistance of the liquid to the passage of the ion is the same for different strengths of solution, the velocity of the ion will be the same for different strengths, but the quantity of it, and therefore the quantity of electricity which passes in a given time, will be proportional to the strength of the solution.

Now, Kohlrausch has determined the conductivity of the solutions of many electrolytes in water, and he finds that for very weak solutions the conductivity is proportional to the strength. When the solution is strong the liquid through which the ions struggle can no longer be considered sensibly the same as pure water, and consequently this proportionality does not hold good for strong solutions.

Kohlrausch has determined the actual velocity in centimetres per second of various ions in weak solutions under an electro-motive force of unit value. From these velocities he has calculated the conductivities of weak solutions of electrolytes different from those of which he made use in calculating the velocity of the ions, and he finds the results consistent with direct experiments on those electrolytes.

It is manifest that we have here important informa-

tion as to the resistance which the ion meets with in travelling through the liquid. It is not easy, however, to make a numerical comparison between this resistance and any results of ordinary diffusion, for, in the first place, we cannot make experiments on the diffusion of ions. Many electrolytes, indeed, are decomposed by the current into components, one or both of which are capable of diffusion, but these components, when once separated out of the electrolyte, are no longer ions—they are no longer acted on by electric force, or charged with definite quantities of electricity. Some of them, as the metals, are insoluble, and therefore incapable of diffusion; others, like the gases, though soluble in the liquid electrolyte, are not, when in solution, acted on by the current.

Besides this, if we accept the theory of electrolysis proposed by Clausius, the molecules acted on by the electromotive force are not the whole of the molecules which form the constituents of the electrolyte, but only those which at a given instant are in a state of dissociation from molecules of the other kind, being forced away from them temporarily by the violence of the molecular agitation. If these dissociated molecules form a small proportion of the whole, the velocity of their passage through the medium must be much greater than the mean velocity of the whole, which is the quantity calculated by Kohlrausch.

On Processes by which the Mixture and Separation of Fluids can be effected in a Reversible Manner.

A physical process is said to be reversible when the material system can be made to return from the final state to the original state under conditions which at every stage of the reverse process differ only infinitesimally from the conditions at the corresponding stage of the direct process.

All other processes are called irreversible.

Thus the passage of heat from one body to another is a reversible process if the temperature of the first body exceeds that of the second only by an infinitesimal quantity, because by changing the temperature of either of the bodies by an infinitesimal quantity, the heat may be made to flow back again from the second body to first.

But if the temperature of the first body is higher than that of the second by a finite quantity, the passage of heat from the first body to the second is not a reversible process, for the temperature of one or both of the bodies must be altered by a finite quantity before the heat can be made to flow back again.

In like manner the interdiffusion of two gases is in general an irreversible process, for in order to separate the two gases the conditions must be very considerably changed. For instance, if carbonic acid is one of the gases, we can separate it from the other by means of quicklime; but the absorption of carbonic acid by quicklime at ordinary temperatures and pressures is an irreversible process, for in order to separate the carbonic acid from the lime it must be raised to a high temperature.

In all reversible processes the substances which are in contact must be in complete equilibrium throughout the process, and Professor Gibbs has shown the condition of equilibrium to be that not only the temperature and the pressure of the two substances must be the same, but also that the *potential* of each of the component substances must be the same in both compounds, and that there is an additional condition which we need not here specify.

Now, we may obtain complete equilibrium between quicklime and the mixture containing carbonic acid if we raise the whole to a temperature at which the pressure of dissociation of the carbonic acid in carbonate of lime is equal to the pressure of the carbonic acid in the mixed gases. By altering the temperature or the pressure very slowly we may cause carbonic acid to pass from the mix-

ture to the lime, or from the lime to the mixture, in such a manner that the conditions of the system differ only by infinitesimal quantities at the corresponding stages of the direct and the inverse processes. The same thing may be done at lower temperatures by means of potash or soda.

If one of the gases can be condensed into a liquid, and if during the condensation the pressure is increased or the temperature diminished so slowly that the liquid and the mixed gases are always very nearly in equilibrium, the separation and mixture of the gases can be effected in a reversible manner.

The same thing can be done by means of a liquid which absorbs the gases in different proportions, provided that we can maintain such conditions as to temperature and pressure as shall keep the system in equilibrium during the whole process.

If the densities of the two gases are different, we can effect their partial separation by a reversible process which does not involve any of the actions commonly called chemical. We place the mixed gases in a very long horizontal tube, and we raise one end of the tube till the tube is vertical. If this is done so slowly that at every stage of the process the distribution of the two gases is sensibly the same as it would be at the same stage of the reverse process, the process will be reversible, and if the tube is long enough the separation of the gases may be carried to any extent.

In the *Philosophical Magazine* for 1876, Lord Rayleigh has investigated the thermodynamics of diffusion, and has shown that if two portions of different gases are given at the same pressure and temperature, it is possible, by mixing them by a reversible process to obtain a certain quantity of work. At the end of the process the two gases are uniformly mixed, and occupy a volume equal to the sum of the volumes they occupied when separate, but the temperature and pressure of the mixture is lower than before.

The work which can be gained during the mixture is equal to that which would be gained by allowing first one gas and then the other to expand from its original volume to the sum of the volumes, and the fall of temperature and pressure is equal to that which would be produced in the mixture by taking away a quantity of heat equivalent to this work.

If the diffusion takes place by an irreversible process, such as goes on when the gases are placed together in a vessel, no external work is done, and there is no fall of temperature or of pressure during the process.

We may arrive at this result by a method which, if not so instructive as that of Lord Rayleigh, is more general, by the use of the physical quantity called by Clausius the Entropy of the system.

The entropy of a body in equilibrium is a quantity such that it remains constant if no heat enters or leaves the body, and such that in general the quantity of heat which enters the body is

$$\int \theta d\phi,$$

where ϕ is the entropy, and θ the absolute temperature.

The entropy of a material system is the sum of the entropy of its parts.

In reversible processes the entropy of the system remains unchanged, but in all irreversible processes the entropy of the system increases.

The increase of entropy involves a diminution of the available energy of the system, that is to say, the total quantity of work which can be obtained from the system. This is expressed by Sir W. Thomson by saying that a certain amount of energy is dissipated.

The quantity of energy which is dissipated in a given process is equal to

$$\theta_0(\phi_2 - \phi_1),$$

where ϕ_1 is the entropy at the beginning, and ϕ_2 that at the end of the process, and θ_0 is the temperature of the system in its ultimate state, when no more work can be got out of it.

When we can determine the ultimate temperature we can calculate the amount of energy dissipated by any process, but it is sometimes difficult to do this, whereas the increase of entropy is determined by the known states of the system at the beginning and end of the process.

The entropy of a volume v_1 of a gas at pressure p_1 and temperature θ_1 exceeds its entropy where its volume is v_1 and its temperature θ_0 by the quantity

$$\frac{p_1 v_1}{\theta_1} \left\{ \frac{1}{\gamma - 1} \log \frac{\theta_1}{\theta_0} + \log \frac{v_1}{v_0} \right\}$$

Hence if volumes v_1 and v_2 of two gases at the same temperature and pressure are mixed so as to occupy a volume $v_1 + v_2$ at the same temperature and pressure, the entropy of the system increases during the process by the quantity

$$\frac{p}{\theta} \left\{ v_1 \log \frac{v_1 + v_2}{v_1} + v_2 \log \frac{v_1 + v_2}{v_2} \right\}$$

Since in this case the temperature does not change during the process, we may calculate the quantity of energy dissipated by multiplying the gain of entropy by the temperature, and we thus find for the dissipation

$$p v_1 \log \frac{v_1 + v_2}{v_1} + p v_2 \log \frac{v_1 + v_2}{v_2},$$

or the sum of the work which would be done by the two portions of gas if each expanded under constant temperature to the volume $v_1 + v_2$.

It is greatest when the two volumes are equal, in which case it is

$$1.386 p v,$$

where p is the pressure and v the volume of one of the portions.

Let us now suppose that we have in a vessel two separate portions of gas of equal volume, and at the same pressure and temperature, with a movable partition between them. If we remove the partition the agitation of the molecules will carry them from one side of the partition to the other in an irregular manner, till ultimately the two portions of gas will be thoroughly and uniformly mixed together. This motion of the molecules will take place whether the two gases are the same or different, that is to say, whether we can distinguish between the properties of the two gases or not.

If the two gases are such that we can separate them by a reversible process, then, as we have just shown, we might gain a definite amount of work by allowing them to mix under certain conditions; and if we allow them to mix by ordinary diffusion, this amount of work is no longer available, but is dissipated for ever. If, on the other hand, the two portions of gas are the same, then no work can be gained by mixing them, and no work is dissipated by allowing them to diffuse into each other.

It appears, therefore, that the process of diffusion does not involve dissipation of energy if the two gases are the same, but that it does if they can be separated from each other by a reversible process.

Now, when we say that two gases are the same, we mean that we cannot distinguish the one from the other by any known reaction. It is not probable, but it is possible, that two gases derived from different sources, but hitherto supposed to be the same, may hereafter be found to be different, and that a method may be discovered of separating them by a reversible process. If this should happen, the process of interdiffusion which we had formerly supposed not to be an instance of dissipation of energy would now be recognized as such an instance.

It follows from this that the idea of dissipation of energy depends on the extent of our knowledge. Available energy is energy which we can direct into any desired channel. Dissipated energy is energy which we cannot lay hold of and direct at pleasure, such as the energy of the confused agitation of molecules which we call heat. Now, confusion, like the correlative term order, is not a property of material things in themselves, but only in relation to the mind which perceives them. A memorandum-book does not, provided it is neatly written, appear confused to an illiterate person, or to the owner who understands it thoroughly, but to any other person able to read it appears to be inextricably confused. Similarly the notion of dissipated energy could not occur to a being who could not turn any of the energies of nature to his own account, or to one who could trace the motion of every molecule and seize it at the right moment. It is only to a being in the intermediate stage, who can lay hold of some forms of

energy while others elude his grasp, that energy appears to be passing inevitably from the available to the dissipated state.

(J. C. A.)

DIGBY, SIR KENELM (1603–1665), an eminent English physical philosopher, born at Gothurst, Buckinghamshire, on the 11th July 1603, was descended from an ancient and illustrious family. His great-grandfather had distinguished himself at Bosworth on the side of Henry VII., and his father, Sir Everard Digby, was one of the leading Roman Catholic gentry at the time of the Gunpowder Plot. Having risen in arms on that occasion, Sir Everard was executed at London, January 27, 1606. The young philosopher was educated by his guardians in the Protestant faith. Having finished his education at Oxford, he went abroad in 1621, and travelled in France, Spain, and Italy. On his return he was knighted, and received from Charles I. the appointments of gentleman of the bed-chamber, commissioner of the navy, and governor of Trinity House. At the head of a small squadron, which he equipped at his own expense, he sailed in 1628 against the Algerines, and afterwards defeated the Venetians near the port of Scanderoon. During a brief stay in Paris he joined the Church of Rome. Having returned to England in 1638, he espoused the cause of the king, and was imprisoned in Winchester House, by order of the Parliament. He was, however, liberated at the request of the French queen-dowager in 1643, and retired to France, where he was taken into the confidence of the court, and enjoyed the friendship of Descartes and other learned men. Here he wrote his *Treatise on the Nature of Bodies*, his *Treatise on the Soul*, *Peripatetic Institutions*, and other works. He visited England, after the defeat of the Royalist party, but the Parliament refused to allow him to remain. Banished from England upon pain of death if he returned, he resumed his residence in France, where he was treated with the highest respect, and was intrusted with an embassy to several of the courts of Italy. He returned again to his native country during the Protectorate of Cromwell, and seemed to be more zealous for the advancement of the interests of the Commonwealth than befitted a staunch royalist. He used his influence to reconcile the Catholics to the Protectorate on condition of their being secured the free exercise of their religion. With Cromwell he was on terms of intimate friendship, the bond of sympathy being probably not so much politics as a common interest in the new-born science of physics. At the Restoration he returned finally to London, where he died in 1665. He married Venetia Anastasia, the daughter of Sir Edward Stanley of Shropshire, “a lady of an extraordinary beauty and of as extraordinary a fame.” His whimsical experiments to preserve her beauty by the invention of now cosmetics procured him as much notoriety as his sympathetic powder for the cure of wounds at a distance. He was appointed one of the council of the Royal Society at the time of its first establishment, and he took a very active part in its management. Besides the works already mentioned, Digby wrote *A Conference about a Choice of Religion*, Paris, 1638; *Letters on the same subject*, Lond. 1651; *Observations on Religio Medici*, Lond. 1643; *A Treatise of Adhering to God*, Lond. 1654; *On the Cure of Wounds by the Powder of Sympathy*, Lond. 1658; and a *Discourse on Vegetation*.

DIGESTIVE ORGANS. The organs of digestion, or alimentary apparatus, are for the purpose of receiving the food or aliment; of converting that portion of the food which is digestible into chyle, so that it may be absorbed and applied to the nourishment of the body; and of transmitting that which is indigestible onwards to be excreted.

In the Protozoa there is no special digestive apparatus,

but the particles of food are introduced into the general substance of the body, where they undergo digestion and assimilation. But in animals generally there is a definite digestive cavity or stomach, which communicates with the surface by a distinct opening or mouth, through which the food is introduced into the stomach. As a rule a second opening, or anus, is also in communication with the stomach, at which the indigestible parts of the food are excreted. As animals increase in structural complexity the digestive apparatus has additional parts superadded to it. In man and all the more highly organized animals it consists of an elongated tube, the Alimentary Canal, divided into various compartments, into which numerous Glands pour their secretions to be used in the digestive process. In most vertebrates, the great class of birds being excepted, the compartment of the canal called the mouth, or oral cavity, contains a hard masticatory apparatus, the Teeth, which play an important part in breaking down the food.

As the digestive organs in the *human body* are so constructed as to illustrate one of the most perfect forms of an alimentary apparatus, they will form the special subject of description in this article.

The ALIMENTARY CANAL is a tube about 28 feet long, which traverses almost the entire length of the axial part of the body. In man and all other vertebrates, it lies in relation to the ventral surface of the bodies of the vertebræ. It commences on the face at the orifice of the mouth, and terminates on the surface of the lower part of the trunk at the orifice of the anus. It is divided into a series of segments, or compartments, which communicate with each other, from above downwards, in the longitudinal axis of the canal. These compartments are named mouth, pharynx, œsophagus, stomach, small intestine (subdivided into duodenum, jejunum, and ileum), and large intestine (subdivided into cæcum, colon, and rectum). The canal is lined by a mucous membrane, called the alimentary mucous membrane, which is continuous with the nasal mucous membrane, with the respiratory mucous membrane, and at the anal and oral orifices with the integument. Outside this mucous membrane is the submucous coat, and external to it is the muscular wall of the canal. By the contraction of the muscular wall the food is propelled along the canal from above downwards. Opening on the surface of the mucous membrane are the orifices of the ducts of numerous glands, the secretions of which, mingling with the food, act chemically on it, so as to render it soluble and capable of being absorbed.

The *Mouth, Oral Cavity, or Buccal Cavity*, is the dilated commencement of the alimentary canal, in which the food is masticated and mingled with the secretion of the salivary and mucous glands. It is situated in the face, and extends from the lips in front to the pharynx behind. It is bounded above by the hard and soft palate, with the uvula; below by the lower jaw, the mucous membrane of the floor of the mouth, and the tongue; on each side by the cheek; and in front by the lips, between which is the aperture of communication with the surface of the face. Behind it freely communicates with the pharynx through the isthmus faucium. The muscles situated in the lips, cheeks, floor of the mouth, tongue, and soft palate enter into the formation of the walls of the mouth.

The mouth is lined by a red-coloured mucous membrane, which becomes continuous posteriorly with that of the pharynx, and at the margins of the lips with the skin of the face. The mucous membrane covering the alveolar portions of the jaws, and surrounding the necks of the teeth, is called the *gum*. From the outer surface of each jaw it is reflected to the inner surface of the cheeks and lips. From the inner surface of the lower jaw the mucous membrane is reflected to the floor of the mouth, and a broad band,

ALIMENTARY
CANAL

called *frænum linguae*, is prolonged to the middle line of the under surface of the tongue.

In its structure the mucous lining of the mouth consists of a stratified pavement epithelium, and a sub-epithelial fibro-vascular corium, possessing numerous vascular papillæ. The mucous membrane of the gum is characterized by its density and toughness, due to the numerous strongly developed bundles of connective tissue in the corium, many of which are continued into the fibrous tissue of the periosteum, which covers the alveolar surface of the jaw. The free surface of the corium of the gum possesses numerous broad papillæ, and is covered by a stratified pavement epithelium similar to that in the lips and cheeks. The mucous membrane of the hard palate is also tense and tough, though not so much so as the gum, and the fibrous fasciculi of its corium blend with the connective tissue of the subjacent periosteum. The mucous lining of the mouth is a sensitive membrane, and receives its nervous supply from the fifth cranial nerve.

The mucous membrane of the mouth is specially modified on the dorsum of the tongue, in the interval between the circumvallate papillæ and the epiglottis, and in the substance of the tonsils, by the development of collections of lymphoid tissue in the sub-epithelial connective tissue.

The *Tonsils* are two almond-shaped bodies, situated, one on each side of the posterior orifice of the mouth, in the fossa between the anterior and posterior pillars of the soft palate. Their normal size is not bigger than a hazel nut, but they are very apt to enlarge, grow inwards across the posterior aperture of the mouth, and diminish the size of that opening. The free surface is marked by several rounded holes, leading into shallow pits or crypts, which may be either simple or branched, in the substance of the tonsil. The pits are lined by the epithelial covering of the mucous membrane, into which minute papillæ project. In the sub-epithelial connective tissue of the walls of the crypts numerous follicles of lymphoid tissue are situated, and lymph cells are infiltrated in great numbers in the connective tissue between the follicles. Interspersed amidst the crypts are small racemose mucous glands. The tonsils are very vascular, and capillary blood-vessels are distributed in connection with the papillæ, the lymphoid tissue, and the racemose glands. The tonsillar veins form a plexus in relation to the attached surface of the tonsil.

FIG. 1.—Vertical section through one of the tonsils, to show a pit vertically divided. *a*, its epithelial lining, *b*, lymph follicles, *c*, *d*, *e*, lymph cells diffused in the connective tissue, *f*, small artery ending in capillary blood-vessels. Slightly magnified.

Mucous and Salivary Glands of the Mouth.—The ducts of numerous glands, engaged in secreting mucus and saliva, open on the free surface of the mucous membrane of the mouth. Their secretion not only keeps the mouth moist, and aids therefore in articulation, but by mingling with the food assists in mastication, deglutition, and the digestive process. Each gland is characterized by being divided into small lobules, and by possessing a duct or ducts, which branch off in an arborescent manner in the substance of the gland, and finally end in the minute lobules. They all belong to the compound racemose group of glands.

The mucous glands of the mouth are situated beneath its mucous lining in the following localities:—(a) *labial* glands, in the upper and lower lips, but absent at the angles of the mouth; (b) *buccal* glands, scattered on the inner surface of the cheek from the lips to the opening of the parotid duct; (c) *palatine* glands, on the oral surface of the hard palate, in the uvula, on both surfaces of the soft palate, and in the

tonsils; (d) *molar* glands, close to the last lower molar tooth on each side; (e) *lingual* glands, extending backwards from the tip of the tongue along its margin, and also on its dorsum between the circumvallate papillæ and epiglottis. The ducts of these mucous glands consist of a delicate membrane lined by a single layer of columnar epithelial cells. The terminal branches of the ducts which enter the lobules end in a series of saccular dilatations, the *acini*, *alveoli*, or *gland-vesicles*, which contain rounded or polygonal secreting cells. A collection of such vesicles forms a lobule. The lobules are bound together by intermediate connective tissue, in which the blood-vessels divide into a capillary network, that ramifies on the outer surface of the delicate membrane forming the wall of the gland-vesicles.

The salivary glands of the mouth are the parotid, submaxillary, and sublingual glands. The *parotid gland* is the largest salivary gland, and occupies the parotid hollow between the lower jaw and the external ear. Its anterior border overlaps the masseter muscle, and the excretory duct emerges out of this border. A prolongation of gland substance, the *socia parotidis*, frequently accompanies the duct for a short distance. The excretory duct of the gland, called *Stenson's duct*, passes forwards superficial to the masseter muscle, then pierces the cheek, and opens on its inner surface opposite the second upper molar tooth. The duct is between 2 and 3 inches long, and about the thickness of a crow-quill. The *submaxillary gland* is situated immediately below the lower jaw. The excretory duct of the gland, called *Wharton's duct*, runs forwards and opens on the floor of the mouth by the side of the *frænum linguae*. The *sublingual* is the smallest of the salivary glands, and lies under the mucous membrane of the floor of the mouth, close to the *frænum linguae*. It possesses from ten to twenty small excretory ducts, the *ducts of Rivinus*, some of which join Wharton's duct, though the greater number open directly on the floor of the mouth near the *frænum linguae*.

Structure.—The ducts of the salivary glands branch and terminate in the lobules,—each terminal duct ending in a series of saccular dilatations, the *acini*, *alveoli*, or *gland-vesicles*, the wall of which, formed apparently of a membrane propria, is continuous with the simple membranous wall of the terminal duct. The terminal ducts are lined by a layer of squamous epithelium, and the gland-vesicles contain the secreting cells.

The blood-vessels are distributed in the interlobular connective tissue, and form a capillary network on the wall of the gland-ducts, and on the wall of the gland vesicles.

The *Pharynx* is an irregularly dilated canal, which forms a common passage, connecting the mouth with the œsophagus, and the nose with the larynx, so as to be subservient to the processes both of deglutition and respiration. Its position and connections have been described under the heading ANATOMY.

The wall of the pharynx consists of three coats—an external muscular and an internal mucous coat, and an intermediate fibrous membrane, which blends with the sub-mucous coat. The *muscular coat* consists of three pairs of circularly arranged muscles, the constrictors of the pharynx; and of two pairs of longitudinally arranged muscles, the stylo-pharyngei and plato-pharyngei, with occasionally a third pair, the salpingo-pharyngei. The constrictor muscles extend from the lateral wall to the middle line of the posterior wall of the pharynx, and are named from below upwards the inferior, middle, and superior constrictors; they lie on three different planes, so that the inferior constrictor overlaps the middle, and the middle the superior.

The *mucous coat* of the pharynx lines the canal, and is

continuous through the several openings with the mucous membrane lining the Eustachian tubes, nose, mouth, larynx, and œsophagus.

The epithelium covering the mucous membrane of the nasal part of the pharynx is columnar and ciliated over a considerable surface, but elsewhere the pharyngeal epithelium is tessellated and stratified, and in the latter localities, vascular papillæ project into the epithelial layers. Small racemose glands lie beneath the mucous membrane, which is pierced by their ducts to open on the surface (fig. 2), they are most numerous in the nasal part of the pharynx. Collections of lymphoid tissue are found in

FIG. 2.—Vertical section through the mucous membrane of the pharynx, to show the racemose glands. *e*, the epithelium, *c*, subjacent connective tissue, *a*, racemose gland, *d*, its duct, *g*, artery ending in a capillary plexus on the gland vesicles. $\times 40$

the sub-epithelial connective tissue, more especially in the nasal part of the pharynx, where it forms a mass, extending across the posterior and upper wall, between the openings of the two Eustachian tubes, which Luschka has called the *pharyngeal tonsil*. The arteries of the pharynx are derived from the external carotid or some of its branches. The motor, sensory, and sympathetic nerves unite to form the pharyngeal plexus situated behind the middle constrictor muscle.

Soft Palate. The *Soft Palate* forms an inclined plane, which projects downwards and backwards into the pharynx, from the posterior border of the hard palate. It is less dependent at the sides than in the mesial plane, where it forms an elongated body, the *uvula*. Its anterior or oral surface is smooth, and gives origin on each side to a fold, which curves downwards to the side of the root of the tongue, to form the *anterior pillars of the palate or fauces*. Its posterior or pharyngeal surface, also smooth, gives origin on each side to a fold, which, springing from the base of the uvula, curves downwards and backwards to be lost in the side-walls of the pharynx; this pair of folds forms the *posterior pillars of the palate or fauces*. The soft palate is complex in structure, and consists of muscles, mucous membrane, glands, blood and lymph vessels, and nerves. The muscles of the soft palate are arranged in two groups, those which elevate and make it tense, and those which constrict the fauces.

The mucous membrane of the soft palate is continuous with that of the mouth and pharynx. The epithelium covering the anterior or oral surface is a stratified pavement epithelium. That on the posterior or pharyngeal surface is in infancy a laminated cylindrical and ciliated epithelium, with isolated areas of pavement epithelium, but in adults it is a laminated pavement epithelium. Numerous racemose mucous glands lie beneath the mucous membrane, but much more abundantly on the oral than on the pharyngeal aspect. Collections of lymphoid tissue, similar to those found in the tonsils, are also met with. The arteries are branches of the internal maxillary, facial, and ascending pharyngeal. The veins of the soft palate often assume a dilated character, and are continuous with the pharyngeal veins. Lymphatics are also distributed beneath the mucous membrane.

Œsophagus. The *Œsophagus*, or *Gullet*, is an almost cylindrical tube, about 9 or 10 inches long, which transmits the food from

the pharynx to the stomach. It commences in the neck opposite the body of the sixth cervical vertebra, where it is continuous with the pharynx. It passes down the lower part of the neck, traverses the cavity of the thorax, pierces the diaphragm at the œsophageal opening, enters the abdomen, and becomes continuous with the cardiac end of the stomach close to that opening.

Structure.—The wall of the œsophagus consists of three coats, named, from without inwards, muscular, submucous, and mucous coats.

The *muscular or external coat* is divided into two layers, an external and an internal. The *external* layer is composed of fibres arranged longitudinally in the wall. The *internal* layer consists of fibres arranged in a series of rings around the tube, which lie sometimes horizontally, at others obliquely. The muscular coat in the upper fourth of the œsophagus is red, and its fibres are transversely striped, in the second fourth numerous non-striped fibres are mingled with the striped; whilst in the lower half the coat consists exclusively of non-striped fibres. By the contraction of the fibres of the muscular coat the food is propelled downwards into the stomach.

The *submucous coat* connects the muscular and mucous coats with each other. It consists of bundles of white fibrous tissue intermingled with elastic fibres, and the nerves and blood-vessels passing to the mucous coat ramify in it.

The *mucous or internal coat* lines the interior of the tube, and is continuous above with the mucous lining of the pharynx, and below with that of the stomach. When the œsophagus is empty it is thrown into longitudinal folds. Its free surface is covered by a thick layer of stratified squamous epithelium, which terminates abruptly at the cardiac orifice of the stomach in an irregular line. Projecting into the epithelium are multitudes of minute conical papillæ. Opening on the surface of the membrane are the ducts of numerous small racemose glands similar to those in the pharynx (fig. 2). Collections of lymphoid tissue, forming solitary follicles, are also found in the mucous membrane. The deep surface of the mucous membrane consists of a layer of non-striped muscular tissue, the bundles of which run longitudinally, it forms the muscular layer of the mucous coat, or *muscularis mucosæ*.

The œsophagus is supplied with blood by the inferior thyroid artery, the œsophageal branches of the thoracic aorta, and the ascending branch of the coronary artery of the stomach. The nerves are derived from the pneumo-gastrics, which form plexuses containing nerve-cells, not only in the muscular coat, but in the *muscularis mucosæ*. A network of lymphatic vessels also occurs in both the mucous and submucous coats.

ABDOMINAL CAVITY AND PERITONEUM.—As the remaining portions of the alimentary canal are situated in the abdominal cavity, it will be advisable, before describing their anatomy, to give an account of the form and boundaries of that cavity, of its division into regions, and of the general arrangement of the peritoneum, which constitutes its lining membrane.

The *Abdominal Cavity*, *Abdomen*, or *Belly*, is the largest of the three great cavities of the body. It occupies about the lower two-thirds of the trunk, and extends from the diaphragm above to the pelvic floor below. As its walls, except in the pelvic region, are chiefly formed of muscles and of fibrous membrane, they are much more distensible than those of the thorax, and permit considerable modifications to occur in the size of the viscera contained within the cavity. The abdomen is elongated in form, its vertical diameter is greater than either the transverse or the antero-posterior diameter. The superior boundary is formed by the concave vault of the diaphragm, and by the seven lower pairs of ribs and costal cartilages; in this boundary occur the opening through which the œsophagus passes into the abdomen, and also the apertures for the transmission of the great blood-vessels, the nerves, and the thoracic duct. The inferior boundary is formed by the levatores ani and coccygei muscles, and the pelvic fascia, in relation to this boundary are the termination of the rectum and anal orifice, the termination

of the urethra, and in the female that of the vagina also. The anterior boundary is formed above by the muscles of the anterior abdominal wall and the fascia transversalis; the linea alba occupies its middle line, and about the middle of the linea alba is the umbilicus or navel, the anterior wall below is formed by the two pubic bones with the symphysis. The lateral walls, or flanks, are formed above by the flat muscles of the abdominal wall and the fascia transversalis, and below on each side by the ilium and ischium with the muscles attached to them. The posterior wall is formed by the lumbar spine, sacrum, and coccyx, and by the muscles attached to these bones with their accompanying fasciae. The abdomen is primarily divided into the *pelvis* and *abdomen proper*. The *pelvis* is subdivided into the *false pelvis*, or the part above the pelvic brim, and *true pelvis*, or part below the pelvic brim.

The *Peritoneum* is the largest and most complicated serous membrane in the body. Like the other serous membranes, it not only lines the walls of the cavity in which it is situated, but gives a more or less complete investment to the contained viscera. It is arranged, therefore, so as to form a *parietal* and a *visceral* part, which are continuous with each other in the various regions where the part lining the wall is reflected as a covering upon the viscera. A space or cavity, called the *peritoneal cavity*, is inclosed between the parietal and visceral layers. This cavity, as in other serous membranes, is a closed or shut sac, without any communication externally, except in the female, where the two Fallopian tubes open into it.

Through these openings the mucous membrane lining the tubes becomes continuous with the serous membrane, and a communication is established between the lumen of each tube and the peritoneal cavity. That surface of both the parietal and visceral portion of the peritoneum which lies next the cavity is free, smooth, covered by an endothelium, and lubricated by a little serous fluid, which under some pathological conditions may be greatly increased in quantity, so as to cause abdominal dropsy. The moistening of the two free surfaces by the serum permits them to glide smoothly on each other, during the movements of the viscera, and the changes which take place in their size and position. The opposite surface of the peritoneum is attached—that of the parietal part to the *fascia* situated internal to the abdominal muscles, that of the visceral part to the *subserous* coat of the several organs.

Special names are applied to the folds or duplicatures of the peritoneum, which pass from the wall of the abdomen to the viscera. In the case of the liver, spleen, bladder, and uterus, these folds are named *ligaments*, whilst the corresponding folds which pass to the intestine have received the name of *mesenteries*. Folds of peritoneum also pass between certain of the viscera themselves, and these are called *omenta*.

The *Stomach* is the bag-like dilatation of the alimentary canal, connecting the œsophagus with the duodenum, in which the food is mingled with the gastric juice, and converted into a pulpy substance—the chyme. The stomach is situated in the costal zone of the abdominal cavity; three-fourths of its volume being contained in the left hypochondrium, whilst the remaining fourth extends into the epigastrium. About five-sixths of the organ lies to the left of the mesial plane, and one-sixth to the right. The stomach varies in size, shape, and somewhat in position, according as it is empty or full of food. When moderately full it is about 1 foot in length, whilst its greatest transverse diameter is 4 to 5 inches. Its general shape is pyriform, and it may be described as possessing two extremities, two surfaces, and two borders. The larger extremity, called the *fundus*, *cardiac extremity*, or *great cul-de-sac*, is directed upwards so as to be in contact with the under surface of the diaphragm, whilst the smaller end, the *pyloric* or *duodenal extremity*, is directed downwards, curves to the right, and becomes continuous with the duodenum. The *surfaces* form the *anterior* and *posterior walls* of the stomach. When the organ is empty, the walls are flattened, and in apposition with each other by their inner surfaces, but when it is distended they are convex. The *borders* of the stomach are curved and unequal in size, one is convex, about three times as long as the other, and is named the *greater curvature*, the other is concave, and forms the *lesser curvature*. The curvatures are so arranged that the greater has its convexity directed downwards and to the left, where it lies in relation to the transverse colon and the splenic flexure of the colon. The lesser curvature has its concavity directed upwards and to the right, and

the œsophagus opens into the stomach at the upper end of the *lesser curvature*. Above this orifice the stomach expands into the *fundus*, which is situated in the highest part of the left hypochondrium, and occupies therefore the summit of the vault of the left half of the diaphragm. At the lower and right end the two curvatures lie almost horizontally in the epigastrium and terminate at the pylorus, where the stomach becomes continuous with the duodenum. The pylorus, or gate of the stomach, is situated in the epigastrium about three fingers' breadth below the ensiform cartilage, and immediately to the right of the mesial plane. The junction of the stomach with the duodenum is marked by a circular constriction externally, called the *pyloric constriction*, and by a valve internally, the *pyloric valve*. At its pyloric end the stomach presents a small bulging, the *lesser cul-de-sac*, or *antrum pylori*.

The stomach is retained in position, partly by its connections with the œsophagus and duodenum, partly by the pressure of the surrounding abdominal walls and viscera, and partly by folds of peritoneum which pass from it to the adjacent structures. These folds are as follows.—The *gastro-phrenic ligament* extends from the diaphragm to the stomach in the angle between the œsophagus and the cardiac extremity; the *gastro-hepatic* or *small omentum* passes from the lesser curvature of the stomach to the lips of the transverse fissure of the liver; the *gastro-splenic omentum* from the cardiac end of the stomach to the spleen, the *gastro-colic* or *great omentum* descends from the greater curvature of the stomach in front of the coils of the small intestine, and then ascends to inclose the transverse colon.

Structure of the Stomach.—The wall of the stomach consists of four coats, named, from without inwards, serous, muscular, submucous, and mucous coats.

The *external* or *serous coat* is that part of the peritoneal membrane which incloses the stomach,—one layer covering the anterior, the other the posterior surface. It leaves the stomach at the curvatures, where it forms the great and small omenta, and along these borders the two layers inclose between them the blood-vessels and nerves which supply the organ.

The *muscular coat* consists of non-striped fibres arranged in three layers from without inwards. The outer layer consists of *longitudinal fasciculi*, which are continuous with the external longitudinal layer of the œsophagus. They form scattered fasciculi extending longitudinally over the surface of the stomach from cardia to pylorus; but along the two curvatures, more especially the lesser, they are collected into stronger bundles, and at the pylorus they become continuous with the longitudinal fibres of the duodenum. The middle layer consists of *circular fasciculi*, which form a ring-like arrangement transversely to the long axis of the stomach. These fasciculi are comparatively thin and scattered at the cardiac end, but as they approach the pylorus they become more closely aggregated, so as to form a thick layer, which at the pylorus extends into the pyloric valve, and forms the *sphincter pylori* muscle. The circular fibres of the stomach are in the same morphological plane as the circular fibres of the œsophagus and duodenum. The inner layer consists of *oblique fasciculi*, which are not found over the entire organ; the greater number spring from the left side of the cardiac orifice, and radiate on the anterior and posterior surfaces towards the pylorus and greater curvature. These oblique fibres by their contraction approximate the cardia to the pylorus, the great curvature to the smaller, and the anterior to the posterior wall; they are thus the true grinding muscles of the stomach, and have been compared to the muscular gizzard of the bird. From the relation of the two groups of oblique fibres to the cardiac orifice they probably close that opening during gastric digestion. The longitudinal and circular fibres

occasion a longitudinal shortening and transverse constriction of the stomach. By the action of the muscular coat the food is churned about in the stomach, so as to become thoroughly intermingled with the gastric juice. The contraction of the sphincter pylori closes the pyloric orifice, and prevents the passage of the food into the duodenum, before it is converted into chyme.

The *submucous coat* consists of the areolar variety of connective tissue, and lies immediately subjacent to the bluish layer of the muscular coat.

The *mucous* or *internal coat* lines the cavity of the stomach, and is continuous with the mucous membrane of the œsophagus and duodenum. It is a soft, pulpy membrane, of a pink colour, which becomes redder during digestion, owing to turgescence of the blood-vessels. At the pyloric end it is often stained yellow or green with bile, and in old people it has a brown colour, from formation of pigment. In the empty stomach it is thrown into folds or *rugæ*, which have usually a longitudinal direction, but when distended the rugæ are obliterated, and the surface of the mucous membrane is smooth. This membrane is commonly said to be thicker at the pyloric end than in the fundus; but Brinton, who had opportunities of examining the stomach of healthy young adults immediately after death, found the cardiac mucous membrane to be more than twice as thick as the pyloric. He ascribes the thinning of the cardiac mucous membrane to the effects of post-mortem digestion, owing to the gravitation of the gastric juice, in the recumbent position of the dead body, into the fundus of the stomach.

If the free surface of the gastric mucous membrane be examined with a pocket lens it will be seen to be pitted with shallow depressions or alveoli, polygonal in form, and varying from $\frac{1}{100}$ th to $\frac{1}{50}$ th inch in diameter. In the sides and bottom of each of these pits numerous rounded orifices may be seen, which are the mouths of the gastric secreting glands. If vertical sections be now made through the mucous membrane, these glands will be seen to be tubular in form.

In the human stomach the tubular glands are, for the most part, simple, almost straight cylinders, and possess an average length of $\frac{1}{2}$ th inch, and a breadth of about $\frac{1}{30}$ th inch. They are somewhat dilated at their orifices, and at their closed ends give rise to cœcal pouches. For about the upper fourth or fifth of their length the tubes are lined by a single layer of columnar epithelium, continuous with the columnar epithelium covering the free surface of the gastric mucous membrane. In the rest of the gland-tube Brinton found two kinds of cells. The one, the so-called *peptic cells*, about $\frac{1}{100}$ th inch in diameter, and of an ovoid or somewhat polygonal form, lay next to the wall of the gland. The other kind, somewhat cubical in form, lined the very narrow central canal of the gland, and formed an *axial layer*, which was continuous above with the columnar epithelium lining the upper end of the tube.

It is in the dog and cat, however, that the structure of the gastric mucous membrane has especially been studied, and two kinds of glands have been described. The one, situated especially in the region of the pylorus, consists for the most part of simple tubes, which may, however, branch at their deeper end; they have been called the *mucous glands*. They are lined by a columnar epithelium, the cells of which at the deeper end of the gland are more cubical in form, and have a clouded granular appearance. The other kind of gland is situated in the remaining part of the gastric mucous membrane, and consists of tubes which divide usually into four branches; they have been named the *peptic glands*. The cellular lining of these peptic glands closely corresponds with the dimorphous arrangement in the human stomach already referred to. Heidenhain

states that in a fasting dog the glands are shrunken, and the axial cells are transparent, whilst during digestion the peptic glands are swollen out and the cells are clouded and granular.

The gastric glands are separated from each other by slender prolongations of the muscularis mucosæ, and by the vascular interglandular connective tissue, which is soft and delicate, and contains a small proportion of lymphoid corpuscles diffused in it. In some localities the lymphoid tissue may be collected into solitary follicles, forming the *lenticular glands* of the stomach. Beneath the glands is a well-defined *muscularis mucosæ*, arranged in two layers, which gives off bundles that pass between the gastric glands.

The gastric mucous membrane is highly vascular, small arteries enter it from the submucous coat, and terminate in a capillary plexus, situated in the interglandular connective tissue surrounding the gastric glands; a vascular capillary ring surrounds the orifice of each gland.

The *pyloric valve* is the name given to the circular fold, situated at the junction of the stomach and duodenum, which surrounds the pyloric orifice. This fold is covered on its free surface by mucous membrane, which incloses the submucous coat and the circular layer of the muscular coat, but not the longitudinal layer, or the serous coat. That portion of the mucous membrane which covers the gastric surface of the valve possesses the structure of the mucous membrane of the stomach; whilst that which covers the duodenal surface is studded with villi, and possesses the structure of the intestinal mucous membrane.

The arteries of the stomach form arches along the greater and lesser curvatures, and anastomose in the anterior and posterior walls of the stomach. The veins of the stomach are rootlets of the portal vein. The lymphatics are numerous, and form a superficial and a deep set. The nerves of the stomach are derived from the epigastric plexus of the sympathetic and from the pneumogastric nerves.

The *Intestinal Canal*, *Intestine*, *Gut*, or *Bowel*, is situated in the abdominal cavity, and extends from the pyloric opening, or gate, of the stomach to the orifice of the anus. In it the chyme becomes mingled with the bile, the pancreatic fluid, and the secretions of the intestinal glands, and is converted into chyle. In it also the absorption of the chyle takes place, and the insoluble part of the food is passed onwards to be excreted in the form of feces. The intestine is the longest division of the alimentary canal, and measures on an average about 25 feet. It is primarily divided into two parts, called small intestine and large intestine, the length of the small is about 20 feet, that of the large about 5 feet.

The *Small Intestine* is the upper of the two divisions of the canal, and consists of a convoluted, almost cylindrical tube, which reaches from the pylorus to the cæcum, or commencement of the large intestine. It is subdivided into three portions, named duodenum, jejunum, and ileum.

The *Duodenum* is the commencement of the small intestine, and has received its name from its length being regarded as about equal to the breadth of twelve fingers. It forms the shortest and widest of the three subdivisions of the small bowel; it curves, in the form of a horse-shoe, from the pylorus to opposite the left side of the body of

Intestinal canal.

Small intestine.

the second lumbar vertebra, where it becomes continuous with the jejunum. The duodenum is distinguished from the rest of the small intestine by having the ducts of the liver and pancreas opening into its canal, by containing in its wall a collection of compound racemose glands, named the glands of Brunner, and by being developed from the primitive fore-gut, and not, like the jejunum and ileum, from the primitive middle gut. Like the stomach, it should be regarded as a distinct segment of the alimentary canal.

The *Jejunum* and *Ileum* form by far the longest part of the small intestine, and are not separated from each other by any sharp line of demarcation—the upper two-fifths being called jejunum, on account of its being usually empty after death, the lower three-fifths being termed ileum, from its convoluted arrangement. They occupy the umbilical, hypogastric, right and left iliac regions of the abdomen, in which they are arranged in a series of coils or convolutions; one or two coils of the ileum sometimes lie in the cavity of the pelvis, between the bladder and rectum. The coils are attached to the posterior wall of the abdomen, along a line from the body of the first lumbar vertebra to the right sacro-iliac joint, by the fold of peritoneum called the *mesentery*. Owing to the extent of the mesentery, the coils of the jejunum and ileum can be freely moved about in the abdominal cavity, so that they are apt to be displaced from their natural position, and, when a rupture occurs, to become the most usual contents of the hernial sac. The lower end of the ileum passes into the right iliac fossa, where it becomes continuous with the large intestine, at the junction of the cæcum and ascending colon. Though the line of demarcation between jejunum and ileum is an arbitrary one, yet the upper end of the jejunum may be distinguished from the lower end of the ileum by being wider, and having a thicker mucous membrane, in which the folds called *valvule conniventes* are larger and more numerous.

Structure of the Small Intestine—The wall of the small intestine consists in the greater part of its extent of four coats, named, from without inwards, serous, muscular, submucous, and mucous coats.

The *serous or external coat*, derived from the peritoneum, forms a complete investment for the jejunum and ileum, and is continuous with the mesentery along a line of attachment, named the mesenteric border of the intestine; but the serous covering of the duodenum is incomplete.

The *muscular coat* consists of non-striped fibres arranged in two layers from without inwards. The outer layer consists of *longitudinal* fasciculi, which form a thin layer parallel to the long axis of the intestine. The inner layer consists of *circular* fasciculi arranged around the gut transverse to its long axis; this layer is thicker, stronger, and more highly coloured than the longitudinal layer. By the contraction of the muscular coat, the peristaltic or vermicular movement is produced, which propels the ingested materials along the intestine.

The *submucous coat* lies immediately subjacent to the circular layer of the muscular coat, and consists of areolar connective tissue, in it the blood-vessels ramify before they pass into the mucous membrane.

The *mucous or internal coat* is a soft, velvety-looking membrane, which lines the wall of the small intestine, and possesses a complex appearance and structure. The inner surface is not smooth, but is thrown into strongly-marked, transverse folds, the *valvule conniventes*, which are not obliterated during distension of the gut. They are very numerous in the duodenum and jejunum, but then decrease in size and numbers, until at the lower end of the ileum they have disappeared. Each valvula consists of a fold of the mucous membrane with its submucous coat. Owing to

their presence, the extent of the mucous surface is much greater than if it were a plane-surfaced membrane.

In its more minute structure the mucous coat may be regarded as composed of numerous projecting bodies, a glandular layer, and a muscular layer.

The projecting bodies are the intestinal *Villi*, which jut out into the lumen of the intestine from the free surface of the mucous membrane, not only of the valvulae, but of the intermediate surface. They are delicate, minute processes, varying in length from a fourth to half a line, and in number amount to several millions.

They are best examined when the mucous surface is placed in water or spirit, when they may be seen with the naked eye, or, still better, with a pocket lens; when the chyle-vessels or blood-vessels are injected, they become erected, and stand out more prominently from the surface. They vary in form, being filiform, or cylindrical, or conical, or club-shaped, or leaf-shaped. They are more numerous in the duodenum and jejunum than in the ileum, and to their presence is due the velvety appearance of the mucous surface. They are not found elsewhere than in the small intestine.

As they are the parts of the mucous membrane directly concerned in the absorption of the chyle, their structure is interesting and important. Each villus is invested by a cap of epithelium continuous with the general epithelial covering of the mucous membrane. The epithelium consists of a single layer of *columnar cells*, compactly arranged side by side. Scattered amidst the columnar cells are cells which possess the form of microscopic goblets, and are named *goblet cells*. The free end of each goblet cell appears to have an open mouth on the surface of the villus, through which a mucus-like substance exudes. Various opinions have been expressed as to the nature of these goblet cells. Some regard them as special structures engaged either in the absorption of chyle, or the secretion of mucus; others look upon them as merely modifications of the columnar epithelium, whilst others again consider them to be *post-mortem* productions, due to the swelling out of the columnar epithelium by the imbibition of fluid. There can be no doubt, however, that they are not specially concerned in the absorption of chyle, as cells of the same character are found in the respiratory mucous membrane, and on other surfaces, where the absorption of chyle does not take place.

The sub-epithelial tissue of a villus forms its matrix or basis substance, and consists of the sub-epithelial connective tissue of the mucous membrane. When thin sections through a villus are examined, the matrix is seen to be

FIG 4.—A transverse section through an intestinal villus, showing its epithelial investment and the matrix of lymphoid tissue, c, columnar epithelium, g, goblet-shaped cell, l, lacteal, r, r, lymphoid retiform tissue, t, t, transversely divided blood-vessels. B, free ends of columnar epithelium, with mouths of four goblet-shaped cells. $\times 300$

composed of a delicate retiform tissue, which forms a network, in the meshes of which numbers of colourless lymphoid corpuscles are imbedded. These cells were described and figured by Goodsir, as the absorbing cells or vesicles of the villus. In the axis of the villus one, or perhaps two, minute lacteals or chyle vessels are situated, which serve as rootlets of origin of the lacteal division of the lymph vascular system. The lacteal is a capillary tube.

which ends near the apex of the villus, as a dilated microscopic *cul-de-sac*. By its opposite extremity it becomes continuous with a plexus of lacteals in the submucous coat. In the matrix substance, around the lacteal vessel of the villus, is a layer of non-striped muscular fibre-cells, which is continuous with the general muscular layer of the mucous coat, and extends as far as the apex of the villus. By the contraction of this layer the chyle during absorption is propelled along the lacteal vessel. The villus also contains blood-vessels; a small artery enters at its attached base, and terminates in a capillary plexus, situated in the peripheral part of the matrix, close to the cap of epithelium; from the plexus a vein arises, which leaves the villus at its base, and joins the veins in the submucous coat.

Various theories have been put forward to account for the mode of passage of the chyle, during digestion, from the lumen of the intestine into the lacteal vessels of the villi; but the question cannot even yet be regarded as definitely settled. The appearance of a network of minute tubules within the matrix, extending from the epithelial investment to the lacteal, which Letzerich supposed to be the channels along which the chyle flowed, is doubtless produced by the arrangement of the strands of the retiform tissue. There seems little doubt that both the cells of the epithelial investment and those of the retiform tissue of the matrix become distended with the particles of chyle previous to its passage into the lacteal. The view advanced by Schafer, that the corpuscles in the meshes of the retiform tissue may serve as carriers of the fatty particles of the chyle into the lacteals, is but another mode of expressing the function of these cells advocated thirty years ago by Goolisir.

The mucous membrane of the small intestine is abundantly provided with secreting glands, named the glands of Brunner and of Lieberkühn.

Brunner's glands are confined to the duodenum; they belong to the compound racemose group of glands, and resemble generally in structure the mucous and salivary glands. The minute lobules of these glands lie in the submucous coat, and the excretory duct pierces the mucous membrane to open on the surface. The wall of the duct is formed of connective tissue lined by columnar epithelium. The finest branches of the duct are continuous with the acini or gland-vesicles, and the gland-vesicles contain the secreting cells, which are columnar in form. A plexus of capillary blood-vessels is distributed outside the membrana propria of the gland-vesicles, and lymphatic vessels lie around the lobules. Into the duodenum, about the junction of its descending and horizontal portions, the duct of the pancreas, and the bile duct from the liver, open by a common orifice. These glands may be regarded, therefore, as accessory glands to this portion of the small intestine.

The glands of *Lieberkühn* are distributed throughout the whole length of the mucous coat of the small intestine. They are simple tubular glands, in shape like test tubes,

which lie vertically in the mucous membrane, and form its proper glandular layer (figs 5 and 6). The tubes are microscopic in size, vary in length from $\frac{1}{10}$ th to $\frac{1}{30}$ th of a line, and are sometimes closely set together, but in the localities where the solitary and Peyer's glands occur they are more widely separated. The glands open on the surface of the mucous membrane between the villi; and the opposite end of the tubes is closed and rounded, and reaches close to the muscular layer of the mucous coat. They are lined by a layer of columnar epithelium cells, continuous with the epithelial investment of the villi. The glands are separated from each other by retiform connective tissue, in the meshes of which colourless lymphoid corpuscles exist in considerable numbers; the plexus of capillary blood-vessels, which is distributed outside the membrana propria of the gland tube, lies in this connective tissue.

The connective tissue of the mucous coat is characterized generally by its retiform character, and by the diffusion of colourless lymphoid corpuscles in the meshwork. But in some parts of the mucosa these corpuscles, with their supporting framework of retiform tissue, are collected into distinct masses or follicles, visible to the naked eye, and known as the solitary and Peyer's glands or follicles.

The *solitary glands* are scattered throughout the whole length of the intestinal mucous membrane. They are about the size of millet seeds, and vary in number and distinctness in different individuals. They are globular or ovoid in form, and occasion a slight elevation of the mucous membrane. One pole of the gland lies next the free surface of the mucous membrane, and is in relation to the columnar epithelium covering the mucosa, whilst the opposite pole rests on the submucous coat.

Peyer's glands, or the *agminated glands*, consist of an aggregation of solitary glands or follicles, which are crowded together, so as to form distinct elongated patches, which may vary in length from $\frac{1}{4}$ inch to 3 or 4 inches. The long axis of each patch corresponds to the long axis of the intestine, and the patches are placed opposite to the mesenteric attachment of the bowel. Villi either may

Slightly magnified.

or may not be situated on the surface of the patch, in the intervals between the individual follicles, but Lieberkühnian glands are always found opening on the surface and frequently forming a ring of orifices around each follicle. Peyer's patches are most abundant in the lower end of the

ileum, but diminish in size and numbers in its upper end and in the jejunum, and are absent in the duodenum.

These follicles are lymphoid organs, and are composed of lymphoid or adenoid tissue. The solitary and Peyer's glands, as is the case generally with the lymphoid organs, are more distinct and perfect in structure in infancy and childhood, than in adults or in advanced age.

The *muscular layer* of the mucous membrane lies next to the submucous coat, and consists of non-striped fibres which lie parallel to the surface of the membrane. It passes into the substance of the villi, and lies around the closed end of the glands of Lieberkuhn.

Of the *blood-vessels* of the small intestine, the arteries enter the wall of the jejunum and ileum at its attached or mesenteric border, and are branches from the arcades of the superior mesenteric artery. They run in the sub-serous tissue around the wall of the intestine, then pierce the muscular coat and supply it, they then enter the submucous coat, and form a network from which branches pass into the mucous coat. The veins accompany the arteries, and form rootlets of the superior mesenteric vein.

The *lymph-vessels*, or *lacteals*, may be traced into the wall of the intestine at the mesenteric border, they form a network in the muscular coat, and then enter the submucous coat, where they are very abundant, from this submucous layer offshoots pass through the retiform tissue, which lies between the Lieberkuhnian glands, into the villi. Where the solitary and Peyer's glands are situated, the lacteals, as Frey has pointed out, form a system of anastomosing vessels around the base and mesial part of each follicle.

The *nerves* are derived from the plexuses of the sympathetic, which accompany the branches of the superior mesenteric artery. They form between the two layers of the muscular coat an important plexus, named, after its discoverer, Auerbach's plexus, in which large stellate nerve-cells are intermingled with nerve-fibres, and a similar nervous plexus is found in the muscular coat of the other divisions of the alimentary canal. It supplies and regulates the movements of the muscular coat.

The *Large Intestine*, though not nearly so long as the small intestine, is of much greater diameter. It reaches from the end of the ileum to the orifice of the anus, and is divided into the cæcum with the appendix vermiformis, the colon, and the rectum; whilst the colon is subdivided into the ascending colon, the hepatic flexure, the transverse colon, the splenic flexure, the descending colon, and the sigmoid flexure.

The *Cæcum*, the dilated commencement of the large intestine, lies below the ileum, and occupies the right iliac fossa. It forms a large *cul-de-sac*, closed in below, but communicating freely above with the ascending colon. Opening on the inner and posterior wall of the cæcum is the *appendix vermiformis*, which is a slender hollow prolongation of the bowel, varying in length from 3 to 6 inches. It has the calibre of the stem of a common tobacco pipe, and ends in a free closed extremity, so that, like the cæcum, it is a *cul-de-sac*. It is not generally found in mammals, but is present in man, the orang, certain lemurs, and the marsupial wombat.

The *Colon* extends from the cæcum to the rectum, and forms the longest part of the large intestine. The transverse part of the colon lies immediately below the great curvature of the stomach, but owing to the length of the *transverse meso-colon*, which forms its peritoneal attachment, it not unfrequently undergoes some change in its position, and may hang downwards towards the pelvis, or be elevated in front of the stomach, or thrown to the right or left side.

The sigmoid flexure of the colon is situated in the left iliac fossa, but as the *sigmoid meso-colon*, which forms its

peritoneal attachment, is of some length, it is freely movable, and not unfrequently hangs into the pelvis, or even extends across into the right iliac fossa.

The *Rectum* is the terminal segment of the large intestine, and extends from the sigmoid flexure to the orifice of the anus. It lies in the cavity of the pelvis. It commences opposite the left sacro-iliac joint, and passes at first obliquely downwards and to the right until it reaches the middle line of the sacrum; secondly, it closely follows the curvature of the sacrum and coccyx, lying in relation to their anterior surface, thirdly, when it reaches the tip of the coccyx its terminal or third part inclines downwards and backwards for about $1\frac{1}{2}$ inch to the anal orifice. The anus opens on the surface of the middle line of the perineum, midway between the two ischial tuberosities, and the skin surrounding the orifice is thin, and wrinkled when the opening is closed. Immediately beneath the skin is the *sphincter ani externus muscle*, which forms a thin layer of fasciculi, arranged in a series of ellipses around the orifice. The sphincter in its normal condition of contraction simply closes the opening, but, under the influence of the will, a more powerful contraction can be induced, so as to resist the entrance of foreign bodies into the rectum.

The large intestine is arranged in the abdominal cavity in the form of an arch, the summit of which is the transverse colon, whilst the cæcum and rectum are the right and left piers. Within the concavity of this arch the coils of the jejunum and ileum are situated. The large intestine is not, except in the rectum, a cylindrical tube, but is dilated into three parallel and longitudinal rows of sacculi, which rows are divided from each other by longitudinal muscular bands, whilst the sacculi in each row are separated externally by intermediate constrictions. In the rectum the sacculi have disappeared, and the intestine assumes a cylindrical form, but at its lower end it dilates into a reservoir, in which the feces accumulate prior to being excreted.

At the junction of the large with the small intestine a valvular arrangement, termed the *ileo-cæcal* or *ileo-colic valve*, is found. This valve is due to the peculiar manner in which the ileum opens into the large intestine.

The opening is bounded by two semi-lunar folds, which project into the large bowel. These folds are the two segments of the valve; one situated above the opening is the *ileo-colic segment*, the other, below the opening, the *ileo-cæcal*. The two segments become continuous with each other at the ends of the elongated opening, and are prolonged for some distance around the inner wall of the large intestine as two prominent ridges, named the *fræna* of the valve. The use of the ileo-cæcal valve is to impede or prevent the reflux of the contents of the large into the small intestine. When the cæcum and colon are distended the fræna of the valve are put on the stretch, and the two segments are approximated, so that the opening is reduced to a mere slit, or even closed, if there is great distension of the bowel.

Structure of the Large Intestine.—The wall of the large intestine consists in the greater part of its extent of four coats, named, from without inwards, serous, muscular, submucous, and mucous coats.

The *serous* or *external coat*, derived from the peritoneum, forms a complete investment for the flexures of the colon, the transverse colon, and the first part of the rectum, but not for the cæcum, or the ascending and descending colon. The second part of the rectum has only a partial serous investment, and the third part has no serous coat. Numerous pedunculated processes invested by the serous membrane, and containing lobules of fat, named *appendices epiploicæ*, are attached to the large intestine.

The *muscular coat* consists of non-striped fibres arranged

in two layers from without inwards. The outer layer consists of *longitudinal* fasciculi, which are not as a rule distributed uniformly in the wall, but in the cæcum and colon are collected into three longitudinal bands, which start from the cæcum, where it is joined by the appendix vermiformis, and extend along the colon to the rectum. As these bands are not so long as the colon itself, they occasion the puckerings which separate the sacculi, so that when the bands are cut through the sacculi disappear. The colon then becomes more elongated and cylindrical.

In the appendix vermiformis the longitudinal layer is not collected into bands, but arranged uniformly along the wall. In the rectum, also, the longitudinal layer is spread uniformly along the wall, and forms a well-defined *recto-colonoid* layer.

The inner layer of the muscular coat consists of *circular* fasciculi distributed around the wall of the large intestine. In the rectum this layer increases in thickness, and in proximity to the anus forms a circular muscle, the *sphincter ani internus*, which is a strong band, about half an inch broad, around the lower end of the rectum. In the large, as in the small intestine, the muscular coat occasions the peristaltic movements, and its increased thickness in the rectum is for the purpose of expelling the feces.

The *retro-colonic* coat has similar relations and structure to the corresponding coat in the small intestine.

The *superior* or *internal* coat is not thrown into valvular convolutions, but presents a series of well marked permanent ridges, lying transversely or somewhat obliquely to the long axis of the gut, and depending internally to the constrictions, which, on the outer surface of the colon, separate the *ceci* from each other. The mucous membrane of the large intestine is covered by a layer of columnar epithelium. It is devoid of villi, and consists of a glandular and a muscular layer. The excreting glands of the glandular layer have the form and structure of the Lieberkuhnian glands of the small intestine (fig. 7); they open on the free surface of the mucous coat, and, owing to the absence of villi, their mouths are more closely set together than is the case with the corresponding glands in the small intestine; the tubular glands are separated by a retiform tissue with lymphoid corpuscles. Solitary glands, similar to those in the small intestine, are also present, but no Peyer's patches. The muscularis mucosæ resembles generally that of the small intestine.

Of the *blood vessels* of the large intestine, the arteries are principally derived from branches of the superior and inferior mesenteric arteries, but the lower end of the rectum receives the hemorrhoidal branches of the internal iliac and the pudic. The veins which correspond to these arteries for the most part join the superior and inferior mesenteric vein, and are consequently *portals* of the portal. But the veins which belong to the middle and inferior hemorrhoidal arteries form a plexus about the anal orifice, which partly joins the superior hemorrhoidal vein, and through it the portal vein, and is partly connected through the middle and inferior hemorrhoidal veins with the internal iliac vein, and through it with the inferior vena cava. The veins about the anus are very apt to become varicose, and to form the excrescences termed hemorrhoids or piles. The *lymph vessels* are arranged as in the small intestine, except that they are not prolonged into villi. Nervous plexuses with ganglion cells are found in both the muscular and submucous coats. They proceed from the superior and inferior mesenteric plexuses, but the rectum receives branches from the hypogastric plexus, and from the third and fourth sacral spinal nerves.

The LIVER is the biggest of the abdominal viscera, and the largest gland in the body. It is the organ in which the secretion of bile takes place, and is the chief seat in the

body of the formation of glycogen, a substance like dextrin, which readily undergoes conversion into sugar. It lies in the costal zone of the abdomen, fills up the greater part of the right hypochondrium, and extends, through the epigastrium, into the left hypochondrium. In its long or transverse diameter it averages about 12 inches, in its antero-posterior diameter about 6 inches, in the vertical diameter of its thickest part about 3 inches. Relatively to the size of the body the liver is bigger and heavier in the fœtus than in the adult; soon after birth the relative weight declines, and that of the left lobe diminishes much more rapidly than the right lobe. Frerichs states that the relative weight of the healthy liver fluctuates in adults between $\frac{1}{10}$ th and $\frac{1}{8}$ th of that of the body, and the absolute weight varies from 18 to 46 pounds avoird. During the digestion of the food the liver increases both in size and weight, partly from the greater quantity of blood flowing through it, and partly from the new material in the secreting cells; whilst after a long fast it becomes smaller and lighter.

For descriptive purposes the liver may be regarded as having two surfaces, two borders, and two extremities.

The *superior* or *diaphragmatic surface* is smooth and convex, and attached to the diaphragm by the falciform ligament.

The *posterior* or *vertebral border* is comparatively thick, and attached by the coronary ligament to the diaphragm. The *anterior border* of the liver is unattached, thin, and attenuated, and is marked by a deep notch, opposite the anterior edge of the falciform ligament, which lodges the *round ligament* of the liver.

Of the two *extremities* of the liver the *right* is thick and massive, and lies deep in the right hypochondrium, in contact with the diaphragm; the *left* is thin and attenuated, and overlaps the œsophageal opening and fundus of the stomach.

The *inferior* or *visceral surface* of the liver is much more complex in form than the upper. The *longitudinal* or *umbilical fissure*, continuous with the notch in the anterior border of the liver, and much nearer to the left than the right extremity of the gland, divides it into a large right

FIG. 8.—Under surface of the liver. and a small left lobe. In the anterior part of the fissure the *round ligament*, formed by the obliteration of the umbilical vein of the fœtus, is lodged; whilst the posterior part contains a slender fibrous cord formed by the obliteration of a vein of the fœtus, named *ductus venosus*. The longitudinal fissure is often bridged across by a band of

liver substance called *pars hepatis*. The under surface of the left lobe is smooth, and overlaps the anterior surface of the stomach. The under surface of the right lobe is divided into smaller lobes by fissures and fossae. Starting from about the middle of the longitudinal fissure is the *portal or transverse fissure*, which extends for from 3 to 4 inches across the under surface of the right lobe. It is the gate (*porta*) of the liver, the *hilus* or fissure of entrance into the organ of the portal vein, hepatic artery, hepatic duct, and hepatic nerves and lymphatics. A short distance to the right of that part of the longitudinal fissure in which the round ligament lies, is the *fossa for the gall bladder*, which is a depression on the under surface of the right lobe extending from the anterior border to the transverse fissure in it the gall bladder lies. Extending somewhat obliquely from the posterior border of the liver, towards the transverse fissure, is a deep *fossa for the inferior vena cava*. Opening into the vena cava as it lies in this fossa are the trunks of the large hepatic veins from the substance of the liver. A portion of liver substance, which is bounded by the gall bladder, the longitudinal fissure, the transverse fissure, and the anterior border, forms a four-sided lobe called *lobus quadratus*. Another portion, bounded by the transverse fissure, the posterior border, the vena cava, and the longitudinal fissure, is the *lobus Spiegelii*. A thin prolongation of liver substance continuous with the lobus Spiegelii, and running obliquely between the fossa for the inferior vena cava and the transverse fissure, is the *lobus caudatus*.

Structure of the Liver.—The liver is a solid organ, of a brownish-red colour. It is composed of the ramifications of the portal vein, of the portal capillaries, the hepatic vein, the hepatic artery, the hepatic duct, of secreting cells, nerves, and lymphatics. These several structures are bound together by connective tissue, and the organ is invested by the peritoneum. The liver possesses two coats, a serous and a fibrous.

The *serous* or *external coat* is a part of the peritoneal membrane, and forms an almost complete investment for the liver. It is reflected from the transverse fissure as the *gastro-hepatic omentum*, and from the upper surface and the posterior border as the *falciform*, *coronary*, and right and left lateral ligaments of the liver.

The *fibrous coat*, or *tunica propria*, is immediately adjacent to the serous coat. When carefully raised from the liver delicate processes of areolar tissue may be seen to pass from its deep surface into the substance of the organ. At the transverse fissure it is prolonged into the liver as a very distinct sheath, enveloping the portal vein, hepatic artery, hepatic duct, nerves, and lymphatics. This sheath is named the *capsule of Glisson*, and is prolonged throughout the substance of the organ, along the ramifications of the portal vein and the structures that accompany it.

Lobules of the Liver.—To the naked eye the substance of the liver does not present a homogeneous aspect, but is mottled, and mapped out into multitudes of small areas or lobules,—the *hepatic lobules* or *leaflets*. The lobules of the liver are irregular polygons, and vary in size from $\frac{1}{16}$ th to $\frac{1}{2}$ th of an inch. In man and the mammalia generally the lobules are imperfectly separated from each other by the interlobular vessels and duct, and a scarcely appreciable quantity of areolar connective tissue. In the pig, camel, and polar bear, each lobule is circumscribed by a definite capsule of connective tissue.

As a lobule of the liver is a liver in miniature, and as the structure of the entire liver is the sum of the structure of its lobules, it will be necessary to examine with care the constituent parts of a lobule, and the arrangement of the vessels, duct, and nerves which pass to and from it. An hepatic lobule is composed of blood-vessels, secreting cells,

and bile-ducts, with perhaps nerves and lymphatics. The blood-vessels will first be considered.

The *portal vein* conveys to the liver the venous blood from the stomach, spleen, pancreas, gall bladder, and small and large intestine. It ascends to the transverse fissure, and before it enters the liver divides into two branches, one for the right and one for the left lobe. In its course within the liver, the portal vein divides and subdivides after the manner of an artery. It is closely accompanied by the hepatic artery and duct, and, along with them, is invested by the fibrous sheath, called *Glisson's capsule*. The terminal branches of the portal vein run between the lobules, and are named, from their position, the *interlobular* branches. The interlobular branches lie around the circumference of a lobule, and anastomose with each other. They partly terminate directly in a capillary network situated within the lobule, and partly give off fine branches, which enter the lobule before they end in the capillary network. The *intra-lobular capillaries* form a close network, and converge from the periphery of the lobule, where they spring from the interlobular branches of the portal vein, to the centre of the lobule, where they terminate in the *intra-lobular* or *central vein*, one of the rootlets of the hepatic vein. In man, where the lobules are not separated from each other by a distinct capsule, the capillaries of one lobule to some extent communicate with those of adjacent lobules.

Fig. 9—Transverse section through the hepatic lobules. *i, i, i*, interlobular veins ending in the intra-lobular capillaries, *c, c*, central veins joined by the intra-lobular capillaries. At *a, a* the capillaries of one lobule communicate with those adjacent to it.

The *hepatic artery* closely accompanies the portal vein, and divides into two branches, for the right and left lobes.

It is the nutrient artery of the liver, and gives off three series of branches:—(a) *vaginal branches*, which are distributed to the walls of the portal vein, the hepatic duct, and to Glisson's capsule, probably also to the wall of the hepatic vein; they end in a capillary network in these structures, from which *vaginal veins* arise that terminate in the portal vein; (b) *capsular branches*, which are distributed to the fibrous coat of the liver, and end in a capillary network, from which arise *capsular veins* that join the portal vein; (c) *interlobular branches* of the hepatic artery lie along with the interlobular branches of the portal vein, and end in the capillary network within the lobules.

The *hepatic vein* arises within the substance of the liver from the intra-lobular capillaries. In the centre of each lobule is the *intra-lobular* or *central vein*. It traverses the axis of the lobule, and leaves it to join a small vein running immediately under the bases of adjacent lobules, which, from its position, is named the *sublobular vein*.

Fig. 10—Vertical section through two hepatic lobules of a pig. *c, c*, central veins receiving the intra-lobular capillaries, *s*, sublobular vein, *ch*, interlobular connective tissue forming the capsules of the lobules, *t, t*, interlobular veins.

Adjacent sublobular veins then join together, and form larger vessels, which are the *trunks* of the hepatic vein, or

the *hepatic venous canals*. These trunks run towards the posterior border of the liver, and open into the inferior vena cava.

From this description of the vascular arrangements within the liver, it will be seen that the intralobular capillaries are continuous with three vascular trunks,—two which carry blood to them, the portal vein and the hepatic artery, and one which conveys the blood away from them, the hepatic vein. The communication in each case is so free that the capillaries can be artificially injected from any one of these vessels.

The *secreting cells* of the liver, *hepatic cells*, form the proper parenchyma of the organ. They are situated within the lobules, and occupy the spaces of the capillary network. The cells vary in diameter from $\frac{1}{100}$ th to $\frac{1}{1000}$ th inch; they have the form of irregular polyhedrons, with from four to seven sides, and with the angles sometimes sharp, at other times rounded. They do not appear to possess definite walls, but have a distinct nucleus. The cell protoplasm is granular, and usually contains fat drops, and yellow particles, apparently bile pigment. The general arrangement of the cells is in rows or columns, and when sections are made through a lobule, transverse to the long axis of the central vein, the columns of cells are seen to converge from the periphery to the centre of the lobule, and to form a network.

FIG 11.—Transverse section through lobules of human liver to show the columns of secreting cells, c.c., central veins, i, interlobular vein with a fine sheath of connective tissue $\times 10$.

By many observers the cells are regarded as in contact with the intralobular capillaries, without the intervention of an intermediate membrane. By others, and more especially by Lionel Beale, the secreting cells are regarded as inclosed in a tubular network, the wall of which is formed by a basement membrane. Beale states that the diameter of the network is usually about $\frac{1}{1000}$ th of an inch in most mammals. According to this view, the cells are not in direct contact with the capillary blood-vessels, but separated from them by the basement membrane. In some parts of the lobule Beale has been able to demonstrate the basement membrane as distinct from the wall of the capillaries, but usually they are incorporated together. At the periphery of the lobule the membrane becomes continuous with the wall of the interlobular duct.

The *hepatic* or *bile duct* is the tube that conveys the bile out of the liver. It leaves the transverse fissure as two branches, one from the right, another from the left lobe, which almost immediately unite at an acute angle. It closely accompanies within the liver the ramifications of the portal vein and hepatic artery, and its terminal branches pass between the lobules to form the *interlobular branches* of the duct. If the hepatic duct be injected, not only does the injection fill the interlobular ducts, but it flows into a set of excessively minute passages within the lobules themselves. These passages are arranged so as to form a polygonal network, which may appropriately be called the *intralobular biliary network*. This network has a most intimate relation to the polyhedral hepatic cells, for the passages lie between the flattened sides of adjacent cells, so that each cell is inclosed in a mesh of the network. The German observers, who first directed attention to these passages, named them *bile-capillaries*, but it is probable that they are merely intercellular passages bounded by the protoplasm of the hepatic cells.

The intralobular biliary network differs from the intralobular blood capillary network, not only in the character

of the fluid conveyed, but in other important particulars. The bile passages have a transverse diameter of about $\frac{1}{10}$ th of that of the blood capillaries, the passages are in relation to the sides of the cells, the blood capillaries to their angles, so that the two systems of networks are not in contact with each other, but are separated by intervening hepatic cell substance; the passages have not, in all probability, an independent wall, such as is possessed by the blood capillaries. As these passages can be injected from the hepatic duct, and as they convey bile from the interior of the lobule into the duct, it is obvious that they must be continuous with the lumen of the interlobular branches of the duct, at the periphery of the lobules.

The wall of the larger bile ducts is formed of a fibro-elastic tissue, with a proportion of non-striped muscular fibre; it is lined by a columnar epithelium. Opening into the larger ducts are numerous orifices, which communicate with branched caecal tubes and follicles, situated within and clustered around the walls of the larger ducts, often in considerable numbers. Some of these appendages to the duct doubtless serve as glands for the secretion of mucus, but others are probably, as Beale supposed, mere diverticula of the duct, in which the bile may be temporarily retained, as in the gall bladder.

The *lymphatics* of the liver form a superficial and a deep set. The superficial set ramifies beneath the serous coat, where they form a network. The deep lymphatics accompany the portal vein and hepatic artery as far as the intervals between the lobules, where they form *interlobular lymphatics*, which, like the corresponding branches of the portal vein, run around the lobule.

The *nerves* of the liver arise from the coeliac plexus of the sympathetic and from the left pneumogastric. They accompany the portal vessels in their distribution, and supply the muscular coats of the vessels.

The *Gall Bladder* is a reservoir for the bile, situated in a fossa on the under surface of the right lobe of the liver, and in a notch in its anterior border (fig 8). It is pyriform in shape, its larger end, or fundus, projects beyond the anterior border, its opposite end, or neck, gives origin to the *cystic duct*, which is directed towards the transverse fissure; after a course of $1\frac{1}{2}$ inch it joins the hepatic duct, and forms the common bile duct, *ductus communis choledochus*. At its neck, the gall bladder bends on itself in a sigmoid curve. The gall bladder is 3 or 4 inches long, and can hold from one to two ounces of bile. It is attached to the liver partly by areolar tissue, and partly by the peritoneum, which is reflected over its free surface.

Structure.—In addition to its partial *serous coat*, the gall bladder has a fibrous and mucous coat. The *fibrous coat* consists of interlacing bands of connective tissue, with which non-striped muscular fibres are sparingly intermingled. The *mucous membrane* lining the gall bladder is deeply bile-stained, and presents on its free surface an alveolar appearance, due to the presence of multitudes of minute folds, which form a reticulum with intermediate depressions. The surface is covered by columnar epithelium. The mucous lining of both the neck of the gall bladder and cystic duct is thrown into folds, which in the duct have an oblique direction, and form the spiral valve. Racemose glands, for the secretion of mucus, occur in the wall of the gall bladder, cystic duct, and common bile duct. The gall bladder is supplied with blood by the cystic branch of the hepatic artery. It receives lymphatics and nerves continuous with those which belong to the liver.

The *common bile duct*, formed by the junction of the cystic and hepatic ducts, is about 3 inches long, and conveys the bile into the duodenum. It lies in the gastro-

incisors round and fusiform, in the lower laterally compressed, and sometimes marked by a longitudinal groove. Although the human incisors are, as the name implies, cutting, chisel-shaped teeth, in many mammals the incisors are greatly modified in form, as for example in the tusks of the elephant. The determination of the incisor teeth does not depend, therefore, on their form, but on their position in the jaws. The name incisor is given to all the teeth situated in the pre-maxillary portion of the upper jaw, and in the anterior end of the lower jaw, whatever their shape may be.

The *canine* or *unicuspid teeth*, four in number, one on each side of the mesial plane of each jaw, are placed next the lateral incisors. They are bigger than the incisor teeth, and the upper canines, which are sometimes called the eye-teeth, are larger than the lower; the fangs of the upper canines are lodged in deep sockets in the superior maxillæ, which extend towards the floor of each orbit. The crowns of these teeth are thick and conical; the fangs are long, single, conical, compressed on the sides where they are marked by a shallow groove. In many mammals these teeth are developed into large projecting tusks.

The *premolar* or *bicuspid teeth*, eight in number, two on each side of the mesial plane of each jaw, lie immediately behind the canines, and the upper bicuspid are somewhat larger than the lower. The crown is quadrilateral in form, and convex both on the inner and outer surfaces. It possesses two cusps, of which the outer or labial is larger and more projecting than the inner, palatal, or lingual cusp. The fangs of the upper bicuspid are single and laterally compressed, often bifid at the point into an outer and inner segment; in the lower bicuspid the fangs are rounded, and taper to a single point.

The *molar* or *multicuspid teeth*, twelve in number, are placed three on each side of the mesial plane of each jaw. They are the most posterior teeth, are the largest of the series, and as a rule decrease in size from the first to the last; the crowns of the lower molars are somewhat bigger than those of the upper molars. The last molar tooth does not erupt until the end of puberty, and is called *dens sapientie*, or *wisdom tooth*. The crowns are broad, quadrilateral, and convex both on the inner and outer surfaces. The first and second upper molars have four cusps projecting from the angles of the grinding or masticating surface, and an oblique ridge often connects the large anterior internal cusp with the posterior external cusp; in the upper wisdom teeth, the two inner or palatal cusps are frequently conjoined. The first lower molar has five cusps, the fifth being interposed between the two posterior cusps; in the second lower molar the fifth cusp is usually absent, or only rudimentary in size, but in the lower wisdom tooth it is often present. The fangs of the first and second upper molars are three in number, and divergent; two on the outer or buccal side, one on the inner or palatal side; in the upper wisdom the fangs are frequently partially conjoined, though trifid at the point. The fangs of the first and second lower molars are two in number, an anterior and a posterior, of which the anterior is the larger, they usually curve backwards in the jaw; in the lower wisdom the fangs are usually conjoined, but bifid at the point.

The crowns of all the teeth become more or less flattened by use, so that the incisors lose their sharp cutting edge, and the cusps of the premolars and molars are worn away.

The temporary or milk teeth are smaller than the permanent teeth. They are more constricted at the neck, where the crown joins the fang, especially in the milk molars, the fangs of which also diverge more widely than in the permanent set. The second temporary molar is bigger than the first. The crown of the first upper molar has three cusps, two buccal, one palatal, that of the second

four cusps. The crown of the first lower molar has four cusps; that of the second five, three of which are buccal, two lingual. The temporary teeth lie more vertically in the jaws than the permanent.

The *alveolus*, or socket for the lodgment of the single fanged teeth, is a single socket, in the multi-fanged teeth, the socket is divided into two or three compartments, according to the number of the fangs. The socket is lined by the *alveolo-dental periosteum*, which is continuous at the mouth of the socket with the periosteal covering of the jaw, and with the deeper fibrous tissue of the gum, where it embraces the neck of the tooth. The alveolo-dental periosteum is formed of retiform connective tissue, on the one hand connected with the surface of the cement, on the other with the more fibrous periosteum lining the bony wall of the socket (fig 15). It is vascular, its vessels being continuous with those of the gum, the pulp-vessels, and the bone. It receives nerves from those going to the pulp. The fang fits accurately in the socket, and through a hole at the tip of the fang the blood-vessels and nerves of the tooth pass into the pulp-cavity of the tooth.

Structure of the Teeth.—Each tooth is composed of the following hard structures—dentine, enamel, and cement or crusta petrosa; occasionally other substances, named osteo-dentine or vasodentine, are present. In a tooth which has been macerated, an empty space exists in its interior, called the pulp-cavity, which opens externally through the hole at the tip of the fang; but in a living tooth this cavity contains a soft, sensitive substance named the pulp.

The *Dentine*, or *Ivory*, makes up the greater part of each tooth; it is situated both in the crown, where it is covered by the enamel, and in the fang, where it is invested by the crusta petrosa; whilst the pulp cavity in the centre of the tooth is a cavity in the dentine. The dentine is composed of an intimate admixture of earthy and animal matter in the proportion of 28 of the animal to 72 of the earthy. The animal matter is resolved on boiling into gelatine, the earthy matter consists mostly of salts of lime.

FIG. 13.—Transverse section through the crown of a tooth. p, pulp cavity; d, dentine, e, enamel.

If thin slices through the dentine of a macerated tooth be examined microscopically, it will be seen to consist of a hard, dense, yellowish-white, translucent *matrix*, penetrated by minute canals, called *dentine tubes*. The dentine tubes commence at the pulp cavity, on the wall of which they open with distinct orifices. They radiate in a sinuous manner from the pulp cavity through the thickness of the dentine, and terminate by dividing into several minute branches; this division takes place in the crown of the tooth immediately under the enamel, and in the fang of the tooth immediately under the crusta petrosa. In their course the dentine tubes branch more than once in a dichotomous manner, and give off numbers of extremely minute collateral branches. The transverse diameter of the dentine tubes near the pulp cavity is $\frac{1}{400}$ th inch, but that of their terminal branches is much more minute.

If the dentine be examined in a fresh tooth, the tubes will be seen to be occupied by soft, delicate, thread-like prolongations of the pulp. The passage of processes of the pulp into the dentine tubes was first seen by Owen in the examination of the tusk of an elephant, but the soft contents of the dentine tubes have been made the subject of special investigation by J. Tomes in the human and other mammalian teeth, and have been named the *dental fibrils*.

In sections through the dentine of dried teeth, it is not uncommon to find, near its periphery, irregular, black

the sensitiveness exhibited by the dentine in some states of a tooth is not necessarily due to the passage of nerves into it, but to its connection with the sensitive dentine pulp.

Development of the Teeth—In studying the development of the teeth, not only has the mode of formation of the individual teeth to be examined, but the order of succession of the different teeth both in the temporary and permanent series.

The teeth are developed in the mucous membrane or gum, which covers the edges of the jaws of the young embryo, and their formation is due to a special differentiation in the arrangement and structure of portions of the epithelial and sub-epithelial tissues of that membrane. The enamel is produced from the epithelium, and the dentine, pulp, and cement from the sub-epithelial connective tissue.

The development of the *temporary teeth* will first be considered. If a vertical section be made through the mouth of a young human

FIG. 16—Vertical transverse section through the mouth of a young human embryo. *np*, nasopalatine region, *t*, tongue, *m*, mouth, *l, l, l, l*, lips, *d, d*, primitive dental grooves with epithelial contents in upper gum, *e, e*, alar structures in lower jaws, *e, e*, cuticular epiblast, *h, h*, hair follicles, *e*, epiblast prolonged into the mouth.

embryo about the sixth or seventh week, its cavity may be seen to be lined by a stratified epithelium, continuous with the layer of stratified epulast forming the cuticle of the face. Along the edge of the gum, corresponding in position to that of the future jaws, the epithelium is of some thickness, and an involution of the epithelium into the subjacent connective tissue has taken place. Owing to this involution a narrow furrow or groove in the connective tissue is produced, which constitutes the *primitive dental groove* of Goodsir. This groove is not, however, an empty furrow, but is occupied by the involution of epithelium. The sub-epithelial connective tissue is soft and gelatinous, and abounds in corpuscles, which are especially abundant in the connective tissue at the bottom of the groove, where the *dental papilla* are produced. These papillae are formed, at the bottom of the groove, by an increased development and growth of the corpuscles of the subjacent connective tissue. The base of each papilla is continuous with the subjacent connective tissue, and the apex projects into the deeper parts of the involution of epithelium. As a papilla increases in breadth and length the groove widens and deepens, and the involution of epithelium, increasing in quantity, expands over the apex and sides of the papilla, so as to form a hood-like covering or cap for it. The cap of epithelium constitutes the *enamel organ*, whilst the papilla is the *formative pulp* for the dentine and permanent pulp. Whilst these changes are taking place in the epithelium and the connective tissue at the bottom of the groove, no commensurate widening occurs at its upper part, which remains for a time relatively narrow but retains within

it a narrow string of epithelial cells, continuous on the one hand with the epithelial lining of the mouth, and on the other with the enamel organ. This epithelial string forms the *neck of the enamel organ*. After a time, however, the growth of the connective tissue forming the lips of the primitive groove causes the neck of the enamel organ to atrophy, so that all communication between the enamel organ and the superficial epithelium is cut off, and the embryo tooth, being now completely inclosed in a cavity or sac, formed by the gelatinous connective tissue of the gum, has entered on what Goodsir termed its *saccular stage* of development.

When inclosed in its sac the embryo tooth, though perfectly soft, acquires a shape which enables one to recognize to what group of teeth it belongs. After a time it begins to harden and to exhibit the characteristic tooth structure.

The dental papilla is more vascular than the surrounding connective tissue, from the blood-vessels of which its vessels are derived.

The papilla abounds in cells, which are, in the first instance, rounded and ovoid in shape. Changes then take place in the cells situated at its periphery, which become elongated and branched, and form layers of cells (odontoblasts). Calcification of the protoplasm of these odontoblasts then occurs, and the peripheral layer of the dentine is produced. In contact with the inner surface of the thin film of dentine, a second layer of odontoblast cells is then arranged, which in their turn calcify, and as the process goes on in successive layers of odontoblasts, the entire thickness of the matrix of the dentine and the dentinal sheaths are produced. But the process of calcification does not apparently take place throughout the whole thickness of the protoplasm of the odontoblasts, for, as Waldeyer pointed out, the axial part of the cells remains undifferentiated as the soft dentinal fibrils of the dentine tubes. As these changes are going on in the peripheral layers of the odontoblasts, the central part of the dental papilla increases in quantity, apparently by a proliferation of its cells; nerve fibres are developed

in it, and it persists as the soft pulp of the tooth. The papilla of the tooth has essentially, therefore, the same relation to the formation of dentine that the celluloso-vascular contents of the medullary spaces, in intra-cartilaginous ossification, have to the formation of bone. In both instances the hard matrix is due to a special differentiation of the protoplasm of the formative cells, the dentinal fibrils are the equivalent structures to the soft contents of the lacunae and canaliculi, and the persistent pulp is equivalent to the celluloso-vascular contents of the Haversian canals.

Prior to the embryo tooth becoming sacculated, changes had taken place in the enamel organ. Those cells of the enamel organ which lie next the dental papilla are continuous, through the neck of the enamel organ, with the deepest layer of cells of the oral epithelium, which cells are elongated columns set perpendicularly to the surface on which they rest. Similarly the cells of the deepest layer of the enamel organ are columns set perpendicularly to the surface of the dental papilla. They undergo a greater elongation, and form six-sided prismatic cells, which Kölliker has named the *internal or enamel epithelium*. The cells of the most superficial layer of the enamel organ lie in contact with the vascular connective tissue which encloses the embryo tooth. They form the *external epithelium* of the enamel organ, and slender papillary prolongations of the connective tissue frequently project into this epithelial layer. The cells of the enamel organ, situated between its external and its internal epithelium, become stellate, and form with each other an anastomosing network of cells like those sometimes seen in the gelatinous connective tissue.

After the tooth has become sacculated, and coincident with the transformation of the odontoblast cells of the dental papilla into dentine, calcification begins in the elongated prismatic cells of the internal or enamel epithelium; their protoplasm becomes calcified,

and they become the rods or prisms of the enamel. As the hardening takes place from the periphery to the centre of each cell, the axial portion may, as Tomes pointed out, remain soft for some time in the axis of the enamel rod. With the increase in length, and with the calcification of the cells of the enamel epithelium, the stellate gelatinous cells disappear, and the outer ends of the enamel rods come in contact with the cells of the external enamel epithelium. By some observers the external epithelium is supposed to disappear without undergoing any special differentiation, but by others it is believed to undergo conversion into Nasmith's membrane.

In this manner the crown of a tooth is formed, and it is lodged in a membranous sac formed by the differentiation into a fibro-vascular membrane of the surrounding connective tissue. Whilst within its sac, the crown of the tooth possesses the characteristic form of the group of teeth to which it belongs. After the calcification of the enamel rods is completed, it can undergo no further change either in shape or in increase of size.

Whilst the crown of the tooth is being formed, ossification of the jaws has been going on, and the tooth, with its membranous sac, has become lodged in an alveolus or socket in the jaw, which alveolus is closed in by the gum.

In order that the crown of the tooth may come into use as a masticatory organ, it has to be elevated to the level of the gum, which is absorbed by the pressure, and the crown then erupts into the cavity of the mouth. The process of eruption is due to the development of the fang, which, as it grows in length, elevates the crown of the tooth and forces it outward. The dentine of the fang is developed from the odontoblast cells of the pulp in a manner similar to that already described for the development of the dentine of the crown. The cement or crusta petrosa is developed from the connective tissue lining the alveolus, which forms the alveolo-dental periosteum. It is therefore an ossification in membrane.

As the temporary or milk teeth precede the permanent teeth, their papillae are naturally the first to form. The series of milk-papillae are not, however, simultaneously produced. From the observations of Goodsir, it has been shown that the milk-papilla of the anterior molar in the upper jaw appears about the seventh week; then the canine papilla, the two incisor papillae, and the posterior molar papilla are successively formed, the last making its appearance about the end of the tenth week. The dental papillae in the upper jaw immediately precede the papillae of the corresponding teeth in the lower jaw.

The eruption of the milk teeth into the mouth does not begin to take place until the latter half of the first year of extra-uterine life, and is not completed until between the second and third year. Though variations occur in the date of eruption of each tooth in different children, it may be stated that the incisors usually appear from the seventh to the ninth month, the anterior molars from the twelfth to the sixteenth month, the canines during the seventh to the eighteenth month, the posterior milk molars from two to two and a half years. The milk teeth begin to be shed about the

sixth year by the dropping out of the incisors. The last to be shed are the canines, which do not fall out till the tenth or eleventh year. The shedding of the milk teeth is preceded by the absorption of the fangs. This is effected, as was satisfactorily shown by J.

FIG 22—One-half the lower jaw of a foetus about the 11th or 12th week, showing the dental papillae in the order of their appearance. 1, the first milk molar; 2, the canine, 3 and 4, the two incisors, 5, the second milk molar—From Goodsir.

Tomes, by the agency of a group of cells situated at the bottom of the sockets. As these cells occasion absorption of the tooth tissue, similar to that occurring in the bone tissue from the action of the large multi-nucleated osteo-klast cells, they may appropriately be called *odonto-klasts*.

The development of the *permanent teeth* will now be considered. In the description of the arrangement of the teeth it has been pointed out that the number of teeth in the permanent set exceeds that of the temporary set. The permanent incisors and canines come into the place of the temporary incisors and canines, and the permanent bicuspids succeed the temporary molars, but the permanent molars have no milk predecessors, and are superadded at the back of the dental series.

The development of the *successional permanent teeth*, which are the ten anterior teeth in each jaw, will first be examined. Prior to the period when the lips of the primitive dental groove meet, to produce the saccular stage of dentition of the several temporary teeth, an indentation, or furrow, takes place in the connective tissue adjoining the string of epithelial cells which form the neck of the enamel organ. This furrow constitutes what Goodsir termed the *cavity of reserve*, and it is filled up by epithelial cells continuous with the epithelium of the neck of the enamel organ. As a cavity of reserve is formed immediately behind (i.e., on the lingual side of) each milk tooth, they are ten in number in each jaw, and, except that for the anterior molar, are formed successively from before backwards.

The cavities of reserve are concerned in the production of the permanent successional teeth, and each temporary tooth is replaced by the permanent tooth formed in connection with the cavity of reserve situated immediately behind it (fig 21). The cavities of reserve become elongated, and widened, and pass above the temporary teeth in the upper jaw, and below those in the lower jaw. At the bottom of each a dental papilla forms, the apex of which indentates and becomes covered by the epithelium contained in the cavity, which forms a cap for the papilla, and constitutes the enamel organ for the permanent tooth. The cavity becomes completely closed by the growth of the surrounding connective tissue, and the embryo permanent tooth becomes sacculated. The process of calcification then goes on, in both the enamel organ and dental papilla, in a manner similar to that already described in the temporary teeth. The permanent teeth then become lodged in sockets in the jaw distinct from those of the temporary teeth. The sac of each permanent tooth remains connected with the fibrous tissue of the gum by a slender fibrous band, or *gubernaculum*, which passes through a hole in the jaw immediately behind the corresponding milk tooth. Before the successional permanent tooth erupts, not only should the temporary tooth be shed, but the bony partition between their respective sockets must be absorbed.

The *superadded permanent teeth*, or permanent molars, three in number on each side, lie behind the successional teeth. Their mode of origin is similar to that of the temporary teeth. The primitive groove, occupied by an involution of the epithelial covering of the gum, is prolonged backwards. Three dental papillae successively appear at the bottom of this groove, and the epithelium covering each papilla forms its enamel organ. Legros and Magitot, however, state that the second permanent molar arises in connection with a diverticulum (cavity of reserve) proceeding from the epithelial string of the enamel organ of the first permanent molar, and that the wisdom tooth is formed in connection with a similar diverticulum from the second permanent molar. The embryo tooth becomes sacculated, and goes through the process of calcification similar to what has been described in the other teeth.

The germ of the first permanent molar appears about the sixteenth week of embryo life, that of the second permanent molar not until about the seventh month after birth; whilst that of the wisdom tooth is not formed until about the sixth year. The crown of the

FIG. 24.—A the lower jaw of a child between four and five years old. 5, the last milk molar, with the successional bicuspid tooth in the cavity of reserve immediately below it. 6 and 7, the first and second permanent molars in their sacs. 8, the cavity in connection with which the wisdom tooth is formed. B, the lower jaw of a child about six years old, 6 and 7, the first and second permanent molars. 8, the papilla of the wisdom tooth developed in connection with its cavity 8.—from Goodsir

first molar is the first of the permanent teeth to erupt into the mouth, which it usually does in the sixth year. The incisors appear when the child is seven or eight, the bicuspids when it is nine or ten, the canines about twelve; the second molars about thirteen, and the wisdom teeth from seventeen to twenty five.

In his dentition man is diphyodont as regards his incisor, canine, and premolar teeth, but monophyodont in the molar series.

From the description of the development of the teeth, it will have been seen that a tooth is made up of three hard tissues—enamel, dentine, and cement—and of the soft vascular and nervous pulp. These tissues are not developed from one layer only of the blastoderm. The enamel is of epiblast origin, whilst the dentine, cement, and pulp are derived from the mesoblast. A tooth in its fundamental development, as was long ago pointed out by Goodsir, must be referred to the same class of organs as the hairs and feathers. The enamel of the tooth, like the hair, is produced by a differentiation of the involution of the epithelium of the epiblast, whilst the dentine and pulp resemble the papilla of the hair, in proceeding from the mesoblast. The tooth-sac, like the hair-follicle, is also of mesoblast origin. Whether the cement, as Robin and Magiot have described, be developed by means of a special cement organ, in the interior of the tooth-sac, or be formed, as has been stated in this description, by the alveolo-dental periosteum, it is on either view derived from the mesoblast. As to the origin of Nasmyth's membrane, there is a difference of opinion; some regard it as a special cornification of the external cells of the enamel organ, in which case it would be from the epiblast, whilst others consider it to be continuous with though structurally different from, the cement—homologous, therefore, with the layer of cement, which in the horse, ruminants, and some other mammals covers the surface of the crowns of the teeth.

The tissues of a tooth have not all the same importance in the structure of a tooth. The dentine is apparently always present, but the enamel, or the enamel and cement, may be absent in the teeth of some animals. For example, the tusks of the elephant and narwhal, and the teeth of the Edentata, are without enamel, and in the Rodentia enamel is present on only the anterior surface of the incisors. But though the enamel is not developed, or forms only an imperfect covering for the crowns of these teeth, yet an enamel organ is formed in the embryo jaws. In 1872 W. Turner described a structure homologous with the enamel organ in relation with each of the dental papillae in the lower jaw of a foetal narwhal, but this organ did not exhibit a differentiation into the three epithelial layers, such as occurs in those teeth in which enamel is developed. Since then C. S. Tomes has seen an enamel organ in the embryo armadillo, and has also pointed out that, in teeth generally, enamel organs exist, quite irrespective of whether enamel subsequently does or does not form.

But further, the involution of the oral epithelium, and the coincident formation of a primitive groove, take place not only where the teeth subsequently arise, but along the whole curvature of the future jaws; whilst the production of dental papillae is restricted to the spots where the teeth are formed. Hence it would seem that the inflection of the oral epithelium is not so essential to the development of a tooth as the formation of a papilla. The inflected epithelium marks only a preliminary stage, and it may or may not be transformed into tooth structure. But that which is essential to the formation of a tooth is the production of the papilla which appears at the bottom of the primitive groove (W. T.)

DIGITALIS, or **FOXGLOVE**, a genus of biennial and perennial plants of the natural order *Scrophulariaceae*. The common or purple foxglove, *D. purpurea*, is common in dry hilly pastures and rocky places and by road sides in various parts of Europe; it ranges in Great Britain from

Cornwall and Kent to Orkney, but it does not occur in Shetland or in some of the eastern counties of England. It flourishes best in siliceous soils, and is not found in the Jura and Swiss Alps. The characters of the plant are as follows—stem erect, roundish, downy, leafy below, and from 18 inches to 6 feet or more in height, leaves alternate, crenate, rugose, ovate or elliptic oblong, and of a dull green, with the under surface downy and paler than the upper; radical leaves together with their petioles often a foot in length, root of numerous, slender, whitish fibres, flowers $1\frac{3}{4}$ – $2\frac{1}{2}$ inches long, pendulous, on one side of the stem, purplish crimson, and hairy and marked with eye-like spots within, segments of calyx ovate, acute, cleft to the base; corolla obtuse, with the upper lobe entire or obscurely divided; stamens four and didynamous (see vol. iv. p. 138, fig. 226); anthers yellow and bilobed, capsule bivalved, ovate, and pointed, and seeds numerous, small, oblong, pitted, and of a pale brown. As Parkinson remarks of the plant, "It flowreth seldome before July, and the seed is ripe in August," but it may occasionally be found in blossom as late as September. In one variety, common in gardens, the flowers are white, in another their purple is of a coppery or metallic hue, and not unfrequently in cultivated plants several of the uppermost blossoms may be united together so as to form a cup-shaped compound flower, through the centre of which the upper part of the stem passes. A figure of *D. purpurea* will be found in vol. iv. plate xi. Many species of foxglove with variously-coloured flowers have been introduced into Britain from the Continent. The plants may be propagated by off-sets from the roots, but are best raised from seed.

The foxglove (Ang-Sax. *foxes-clife*, *foxes-glofa*) is known by a great variety of popular names in Britain. In the south of Scotland it is called bloody fingers, further north, dead-men's-bells; and on the eastern borders, ladies' thimbles, wild mercury, and Scotch mercury. Among its Welsh synonyms are *menyg-ellyllon* (elves' gloves), *menyg y llwynog* (fox's gloves), *bysedd cochion* (red fingers), and *bysedd y cwn* (dog's fingers). In France its designations are *gants de notre dame*, and *doigts de la Vierge*. The German name *fingerhut* (thimble) suggested to Fuchs, in 1542, the employment of the Latin adjective *digitalis* as a designation for the plant.

The leaves, gathered from wild plants when about two-thirds of their flowers are expanded, deprived usually of the petiole and the thicker part of the midrib, and dried, constitute the drug *digitalis* or *digitalis folia* of the pharmacopœia. The prepared leaves have a faint odour and bitter taste, to preserve their properties they must be kept excluded from light in stoppered bottles. They are occasionally adulterated with the leaves of *Inula Conyza*, Ploughman's Spikenard, which may be distinguished by their greater roughness, their less divided margins, and their odour when rubbed; also with the leaves of *Symphytum officinale*, Comfrey, and of *Verbascum Thapsus*, Great Mullein, which unlike those of the foxglove have woolly upper and under surfaces. The powder, infusion, and tincture of digitalis are employed both externally and internally; and its active principle, *digitalin*, may further be used for subcutaneous injection. Digitalin, according to Nativelle, is a crystallizable, neutral, inodorous, bitter substance, of the formula $C_{25}H_{40}O_{15}$, insoluble in water and ether, but soluble in alcohol and chloroform. The earliest known descriptions of the foxglove are those given by Fuchs and Tragus about the middle of the 16th century, but its virtues were doubtless known to herbalists at a much remoter period. Gerarde, in his *Herbal* (1597), advocates the use of foxglove for a variety of complaints; and John Parkinson, in the *Theatrum Botanicum*, or *Theater of Plants* (1640), tells us that

DILIGENCE, in law, is the care which a person is bound to exercise in his relations with others. The possible degrees of diligence are of course numerous, and the same degree is not required in all cases. Thus a mere depositary would not be held bound to the same degree of diligence as a person borrowing an article for his own use and benefit. Jurists, following the divisions of the civil law, have concurred in fixing three approximate standards of diligence—viz., ordinary, less than ordinary, and more than ordinary. Ordinary or common diligence is defined by Story (*On Bailments*) as “that degree of diligence which men in general exert in respect of their own concerns.” So Sir William Jones:—“This care, which every person of common prudence and capable of governing a family takes of

his own concerns, is a proper measure of that which would uniformly be required in performing every contract, if there were not strong reasons for exacting in some of them a greater and permitting in others a less degree of attention" (*Essay on Bailments*). The highest degree of diligence would be that which only very prudent persons bestow on their own concerns; the lowest, that which even careless persons bestow on their own concerns. The want of these various degrees of diligence is negligence in corresponding degrees. These approximations indicate roughly the greater or less severity with which the law will judge the performance of different classes of contracts; but English judges have been inclined to repudiate the distinction as a useless refinement of the jurists. Thus Baron Rolfe could see no difference between negligence and gross negligence; it was the same thing with the addition of a vituperative epithet. See NEGLIGENCE.

Diligence, in Scots law, is a general term for the process by which persons, lands, or effects are attached on execution, or in security for debt.

DILKE, SIR CHARLES WENTWORTH (1810–1869), Baronet, born in London, February 18, 1810, was the only son of Charles Wentworth Dilke, proprietor and editor of the *Athenæum*, and was educated at Westminster school and Trinity Hall, Cambridge. He studied law, and in 1834 took his degree of LL.B., but he did not enter upon the practice of his profession. He assisted his father in his literary work, and afterwards gave up much of his time to several of the learned societies. He was for some years chairman of the council of the Society of Arts, and took a prominent part in the affairs of the Royal Horticultural Society. He was one of the most zealous promoters of the Great Exhibition (1851), and a member of the executive committee. At the close of the exhibition he was honoured by foreign sovereigns, and the Queen offered him knighthood, which, however, he did not accept, he also declined a large remuneration offered by the royal commission. In 1853 Dilke was one of the English Commissioners at the New York Industrial Exhibition, and prepared a report on it. He again declined to receive any money reward for his services. He was appointed one of the five royal commissioners for the Great Exhibition of 1862, and soon after the death of the Prince Consort he was created baronet by the Queen. In 1865 he entered parliament as member for Wallingford. In 1869 he was sent to Russia as representative of England at the Horticultural Exhibition held at St Petersburg. His health, however, had been for some time failing, and he died suddenly in that city, May 10, 1869. He was a fellow of the Society of Antiquaries, and a member of other learned bodies.

DILL (*Anethum*), a genus of umbelliferous plants having decomposed leaves; umbels without involucre; yellow flowers, with calices incomplete above; and lenticular fruit, compressed from back to front, flattened at the margin, and presenting on each side three ridges. The common species, *A. graveolens*, is indigenous to the south of Europe, Egypt, and the Cape of Good Hope. It resembles fennel in appearance. Its root is long and fusiform; the stem is round, jointed, and about a yard high, the leaves have fragrant folioles; and the fruits are brown, oval, and concavo-convex. The plant flowers from June till August in England. The seeds are sown, preferably as soon as ripe, either broadcast or in drills between 6 and 12 inches asunder. The young plants should be thinned when three or four weeks old, so as to be at distances of about 10 inches. A sheltered spot and dry soil are needed for the production of the seed in the climate of England. The leaves of the dill are used in soups and sauces, and, as well as the umbels, for flavouring pickles.

The seeds are employed for the preparation of dill-water and oil of dill (valued for their carminative properties), are largely consumed in the manufacture of gin, and, when ground, are eaten as a condiment in the East. See BOTANY, vol. iv. p. 123.

DILLEN [DILLENUS], JOHANN JAKOB (1687–1747), a distinguished botanist, was born at Darmstadt. He was educated at the university of Giessen, where he received his doctor's diploma, but he early turned his attention from medicine to the study of plants. Whilst at Giessen he wrote several botanical papers for the *Ephemerides Naturæ Curiosorum*, and in 1719 he printed there his *Catalogus Plantarum sponte circa Gissam nascentium*, a little octavo volume illustrated with figures drawn and engraved by his own hand, and containing descriptions of many new genera. In the preface he discusses the classifications of Rivinus, Tournefort, Knant, and Ray, the last of which was that adopted by him. In 1718 Dillen became acquainted in Germany with the botanist William Sherard, who invited him to come to England. Soon after his arrival there, in 1721, he took up his abode at Oxford, where Sherard resided. In 1724 he published an enlarged edition of Ray's *Synopsis Stirpium Britannicarum*. In accordance with the will of Sherard, who died in 1728, Dillen was appointed professor of botany at Oxford. He published in 1732, in two volumes folio, with 324 plates executed by himself, the *Hortus Elthamensis*, of which Linnæus wrote—"Est opus botanicum quo absolutius mundus non vidit" That naturalist spent a month with Dillen at Oxford in 1736, and afterwards dedicated to him his *Critica Botanica*. In 1741 appeared the *Historia Muscorum* of Dillen, to whom and his contemporary Micheli (1679–1731) cryptogamic botany owes its origin. He died April 2, 1747, in his sixtieth year. A print from his picture at Oxford is to be seen in Sm and König's *Annals of Botany*, vol. ii. His books and collection of mosses, with many drawings, were bought by his successor at Oxford, Dr Humphrey Sibthorp, and added to the Sherardian Museum.

DILLINGEN, a town of Bavaria, in the circle of Schwaben-Neuburg, on the left bank of the Danube, 24 miles north-west of Augsburg. Its principal structures are the royal palace, formerly the residence of the bishops of Augsburg, the royal gymnasium and Latin school, with a library of 75,000 volumes, five churches, two episcopal seminaries, a Capuchin monastery, a Franciscan nunnery, and a deaf and dumb asylum. The university, founded in 1549, was abolished in 1804, being converted into a lyceum. The inhabitants, who in 1875 numbered 5029, are engaged in cattle-rearing, the cultivation of corn, hops, and fruit, ship-building and the shipping trade, and the manufacture of cloth, paper, and cutlery. Dillingen was taken by the Swedes in 1632 and 1648, by the Austrians in 1702, and on the 18th July 1800 by the French.

DIMENSIONS. In geometry a line is said to be of one dimension, a surface of two, and a solid of three dimensions. The use of the word is extended to algebraical terms, which are said to be of n dimensions with respect to any quantity when that quantity enters to the n th power.

If the term contains several variables, x, y, z , &c., and if the sum of the indices of these variables is n , the term is said to be of n dimensions with respect to the system of variables x, y, z .

If all the terms of an equation are of n dimensions with respect to the system of variables x, y, z , the equation is said to be homogeneous of n dimensions with respect to that system of variables.

The equation may or may not be homogeneous with respect to another system of variables which occur in it, as p, q, r .

If all the variables of a system with respect to which the equation is homogeneous are increased in the same ratio, the equation will still be true.

The general equations occurring in the application of mathematics to natural phenomena are equally true whatever units we employ for the measurement of the different quantities which enter into them, provided we employ the same units throughout the equation. Hence such equations must be homogeneous with respect to any system of variables which is referred to the same unit, and all quantities essentially numerical, such as exponents and exponentials, logarithms, angles, and circular and elliptic functions, must be of zero dimensions.

There are two methods of interpreting the equations relating to geometry and other concrete sciences.

We may regard the symbols which occur in the equation as of themselves denoting lines, masses, times, &c.; or we may consider each symbol as denoting only the numerical value of the corresponding quantity, the concrete unit to which it is referred being tacitly understood.

If we adopt the first method we shall often have difficulty in interpreting terms which make their appearance during the calculations. We shall therefore consider all the written symbols as mere numerical quantities, and therefore subject to all the operations of arithmetic during the process of calculation. But in the original equations and the final equations, in which every term has to be interpreted in a physical sense, we must convert every numerical expression into a concrete quantity by multiplying it by the unit of that kind of quantity.

Thus if we write $[L]$ for the unit of length, that is to say, the actual concrete centimetre or foot, and if x denotes the numerical value of a certain line, then the complete expression for the line is $x[L]$; and if y, z , &c., are the numerical values of other lines, then the complete expression for the quantity whose numerical value is $x^\alpha y^\beta z^\gamma$ is

$$x^\alpha y^\beta z^\gamma [L^{\alpha+\beta+\gamma}],$$

and this quantity is said to be of $\alpha + \beta + \gamma$ dimensions with respect to $[L]$, the unit of length.

There must be as many different units as there are different kinds of quantities to be measured, but in all dynamical sciences it is possible to define these units in terms of the three fundamental units of length, time, and mass. We therefore suppose these three fundamental units to be given, and deduce all the others from these by the simplest attainable definitions.

The equations at which we arrive must be such that a person of any nation, by substituting for the different symbols the numerical values of the quantities as measured by his own national units, would obtain a true result.

This can only be the case if the equation is homogeneous with respect to each of the fundamental units. To ascertain if it is so we must count the dimensions of every term, and for this purpose we must know the dimensions of any derived units which enter into the equation. The theory of the dimensions of physical quantities were first stated by Fourier, *Théorie de Chaleur*, sec. 160.

By knowing the dimensions of any quantity we are able at once to deduce its numerical value as expressed in terms of one system of units from its numerical value as given in terms of another system.

Thus, magnetic measurements have been made according to the British system, in which the foot, the grain, and the second of mean time are the fundamental units. Other magnetic measurements have been made according to systems derived from the French metric system, using the metre, centimetre, or millimetre as unit of length, the kilogramme, gramme, or milligramme as unit of mass, and the second as unit of time. In recent times an effort has

been made to procure the adoption for all scientific measurements of a system in which the centimetre, gramme, and second are the units. This is sometimes referred to as the C. G. S. system, and a copious list of examples of the measurement of physical quantities on this system, of its comparison with other systems, and of the dimensions of quantities occurring in all branches of physics, has been prepared by Dr Everett, and published by the Physical Society of London and by Taylor and Francis, under the title *Illustrations of the C. G. S. System of Units*.

The three fundamental units may be selected each independently of the others, in an entirely arbitrary manner. It is possible, however, by taking advantage of the permanence of the properties of natural substances, so to define the units that one or more of them may be reproduced without reference to any material standard at present existing.

Thus, if the density of a standard substance in a standard state, such as water when at its maximum density under the pressure of its own vapour, is defined as the unit of density, then the unit of mass may be derived from the unit of length, or *vice versa*. In this system, therefore, the dimensions of mass in terms of length are L^3 , or of length in terms of mass, $M^{\frac{1}{3}}$.

We may define the three fundamental units without reference to any actual body, but by means of a natural substance such as water. For if the solid, liquid, and gaseous states of pure water are in equilibrium in a vessel containing no other fluid, the pressure and temperature of the system are determinate. We may therefore define the unit of density in terms of the density of the liquid water under these conditions, and the unit of pressure in terms of the pressure in the vessel. We may deduce the third unit from the law of gravitation, and define the unit of time in terms of the time of revolution of a satellite about a sphere having the unit density at a distance equal to the radius. This time must be calculated from the results of experiments on attraction. Having thus obtained a density, a pressure, and a time, the magnitudes of which are the same under all circumstances, we can derive from them standards of length and mass. For the dimensions of the unit of density $[D]$ are $[ML^{-3}]$, and those of the unit of pressure $[P]$ are $[ML^{-1}T^{-2}]$, so that the dimensions of $[L]$ are $[P^{\frac{1}{2}} D^{-\frac{1}{2}} T]$, and those of $[M]$ are $[P^{\frac{1}{2}} D^{-\frac{1}{2}} T^3]$.

This method of defining the three fundamental units is suggested, not as being at all comparable in point of accuracy with the usual methods, but as being an example of a method independent of the preservation of any material standards, whether artificial, as those kept by Government, or natural, as the earth, and its time of revolution. (J. C. M.)

DINÁJPUR, a district of British India, within the Rájsháhí Knch-Bihar division or commissionership, under the lieutenant-governor of Bengal, is situated between $24^\circ 43' 40''$ and $26^\circ 22' 50''$ N. lat., and between $88^\circ 4' 0''$ and $89^\circ 21' 5''$ E. long. The district, which occupies an area of 4126 square miles, is a triangular tract of country with the acute angle towards the north, lying between the districts of Jalpáiguri and Rangpur on the E., and Purnah on the W.; on the S. it is bounded by the districts of Bográ, Rájsháhí, and Maldah. The country is generally flat, but towards the south becomes undulating, some of the elevations being about 100 feet in height. The district is traversed in every direction by a network of channels and water courses. Along the banks of the Kulik river, the undulating ridges and long lines of mango-trees give the landscape an aspect of beauty which is not found elsewhere.

Dinājpur forms part of the rich arable tract lying between the Ganges and the southern slopes of the Himālayas. Although essentially a fluvial district, it does not possess any river navigable throughout the year by boats of 4 tons burden. Rice forms the staple agricultural product. It consists of three species, the *āman* or winter rice (the great harvest of the year), the *āus* or autumn rice, and the *boro* or spring rice. The *āman* and *āus* rice are each subdivided into several varieties. The other crops are oats, barley, millet, maize, oilseeds, pulses, jute, sugar-cane, betel leaf, tobacco, and vegetables. The imperial road from Barhampur to Dārjiling runs through the district for a distance of about 130 miles, and the new Northern Bengal State Railway intersects the district for about 30 miles. The climate of the district, although cooler than that of Calcutta, is very unhealthy, and the people have a sickly appearance. The worst part of the year is at the close of the rains in September and October, during which months few of the natives escape fever. The average maximum temperature is 92° 3', and the minimum 74° 8'. The average rainfall is 85·54 inches. The population in 1872 amounted to 1,501,924 souls, equal to 364 persons per square mile,—the Hindus forming 46·8 per cent., and the Mahometans 52·8 per cent.

DINAJPUR, the principal town and administrative headquarters of the above district, is situated on the east bank of the Purnabhābā river, in 25° 38' 0" N lat. and 88° 40' 46" E long. The town seems to have declined in importance of late years. In 1808 it was estimated to contain 5000 houses, the census of 1872 returned only 3031. Population in 1872.—Hindus, 5847, Mahometans, 7016, Christians, 99, others, 80.—total (7700 males and 5342 females), 13,042. The disparity in the proportion of the sexes arises from the fact that many of the shopkeepers and traders have houses in the country where they leave their wives and children.

DINAN, a town of France, in the department of Côtes du Nord, about fifteen miles inland, on the left bank of the Rance. The river is navigable for vessels of 150 tons up to the foot of the great granite viaduct which was completed in 1852 across the ravine between the town and the suburb of Lanvallay. The town has a highly picturesque appearance, not only from the position which it occupies on the rocky heights above the river, but also from the numerous remains which it still preserves of the architecture of earlier days. There are considerable portions of the ancient ramparts and towers, the castle of the 14th century still looks down from its height, and many of the houses in the Rue de Jarzuel and the Rue de la Larderie can boast of almost equal antiquity. Of the public buildings may be mentioned the church of St Sauveur, dating from the 12th to the 16th century, the church of St Malo; the town-house, which was formerly a hospital; and the monastery of the Capuchins, now used as a benevolent institution. Besides a good general trade, the inhabitants carry on the manufacture of linen, sailcloth, cotton, thread, beetroot-sugar, and salt. About half a mile from the town are the ruins of the castle and the Benedictine abbey at Lehon, of which the latter is called in the country the Chapelle des Beanmanoirs; near the neighbouring village of St Esprit stands the large lunatic asylum of Les Bas Foins, founded in 1836, and at no great distance is the now dismantled château of La Garaye, which was rendered so famous in the 18th century by the philanthropic devotion of the count and countess whose story is told in Mrs Norton's well-known *Lady of La Garaye*. The principal event in the history of Dinan is the siege by the English under the duke of Lancaster in 1359, during which Duguesclin and an English knight called Thomas of Canterbury engaged in single combat. The memory of the Breton hero's victory

is preserved by the name of the *Place Duguesclin*, which marks the site of the lists. Population in 1872, 7469.

DINANT, a town of Belgium, at the head of an arrondissement in the province of Namur, about twelve miles south of Namur, on the railway between that city and Givet. It occupies a narrow site between the River Meuse and a rocky limestone hill which is crowned by a castle; its streets are consequently short and crowded, and a considerable number of its houses are built on terraces cut out on the declivity. A cathedral of the 13th century, richly decorated in the interior, two hospitals, and a Latin school are its principal buildings; and among its industrial establishments are paper-mills, glass-factories, salt-refineries, oil-mills, flour-mills, and works for the cutting and polishing of the black marble which is quarried in the neighbourhood. Population in 1866, 6423.

Dinant is a place of great antiquity. A church was consecrated there in 558, and a second in 604. It did not, however, rise to any importance till the 11th century. In the 12th century it was reckoned a place of great strength, and had attained considerable wealth by means of its industry, especially in the manufacture of copper wares, which were familiarly known as *Dinanderie*. In 1466 Philip the Good, duke of Burgundy, took and destroyed the town and its fortifications; but, three years later, his successor, Charles, allowed it to be rebuilt. It was taken and pillaged by the French in 1554, and again in 1675. By the treaty of Ryswick in 1697 it was restored to the Bishop of Liège, but it was again taken by the French in 1794, and became the capital of an arrondissement in the department of Sambre-et-Meuse.

DINAPUR, a town and military station of British India, is situated on the right or south bank of the Ganges, and on the East Indian Railway, in the district of Patna, province of Behar, about ten miles west of Patna. The town, which stretches along the river bank for about a mile, consists mostly of thatched cottages, one story high, and is not laid out with regard to order or symmetry. Several handsome villas, however, surround the place—the residences of the European officers and the richer natives. Barracks sufficiently large to accommodate 1200 men are situated in Dinapur. In 1857 the sepoy garrison of the place took part in the mutiny of that year, but after a conflict with the European troops were forced to retire from the town. Population about 18,000.

DINARCHUS (Δῖνᾱρχος), the orator, son of Sostratus, was born at Corinth about 361 B.C. (Ol. 104, 4). Thus, like at least one greater member of the decade, Lysias, this last of the ten Attic orators was not an Athenian citizen. But his career at Athens, as a resident alien, was at least commenced early in life. When not more than twenty-five, he was already active as a writer of speeches for the law courts. He had been the pupil both of Theophrastus and of Demetrius Phalereus, and had early gained a certain fluent force, and a versatile command of style, which gave him some oratorical repute. His first important contact with public life was in 324 B.C. The Areopagus, after inquiry, reported that nine men had taken bribes from Harpalus, the fugitive treasurer of Alexander. Ten public prosecutors were appointed. Dinarchus wrote, for one or more of these prosecutors, the three speeches which are still extant—one "Against Demosthenes," one "Against Aristogiton," one "Against Philocles." The authenticity of the speech against Demosthenes was indeed denied by Demetrius of Magnesia, chiefly on the ground that it is largely composed of matter taken from Æschines. Westermann went further, and doubted the genuineness of all three speeches. But Schafer—who justly remarks that the absence of originality and of character is itself characteristic of Dinarchus—is probably right in accepting the general opinion that they are authentic.

It must always be borne in mind that Dinarchus was a Corinthian, a mere resident alien at Athens, whose sympathies were in favour of an Athenian oligarchy under

Macedonian control. Little as the man's life, so far as we know of it, engages our respect or esteem, his position must at least be broadly distinguished from that of such a man as Æschines, an Athenian citizen who, while his city could still be saved, abetted its enemies—or from that of such a hireling as Demades. In the Harpalus affair, Demosthenes was, beyond all reasonable doubt, innocent, and so, probably, were others of the accused. Yet Hyperides, the most fiery of the patriots, was on the same side as Dinarchus.

Under the regency—for such it really was—of his old master, Demetrius Phalereus, Dinarchus had much political influence. The years 317–306 B.C. were the most prosperous of his life. On the fall of Demetrius Phalereus, Dinarchus withdrew into exile at Chalcis in Eubœa. About 292 B.C. he ventured to return to Attica, and took up his abode with a former associate, Proxenus, in the country, against whom he afterwards brought an action, on the ground that Proxenus had robbed him of some money and plate which he had brought with him. He died at Athens, at the age of about seventy, *ie*, about 291 B.C.

Dionysius held that, out of 85 extant speeches bearing the name of Dinarchus, 58 were genuine,—28 in public causes, 30 in private causes. In addition to the three speeches above mentioned, we have scanty fragments of 88 more which passed, with at least some authors, under his name. The number need not surprise us, when we remember that Suidas speaks of 160 speeches of Dinarchus, and (following Cæcilius probably) allows 60 as genuine. No orator of the Attic decade had so little of an individual style, and to no other, consequently, was alien work so largely ascribed by the Alexandrian critics. Dinarchus imitated by turns the style of Lysias, of Hyperides, of Demosthenes. As Dionysius says of him, οὐδὲν οὔτε κοινὸν οὔτ' ἰδίον ἔσχετο, he had no general stamp of his own, no distinctive trait. He was neither an inventor, like Lysias, Isocrates, and Isæus, nor a perfecter like Æschines, Hyperides, and Demosthenes. He is called by Hermogenes ὁ κριθῦρος Δημοσθένους,—a metaphor taken either from barley compared with wheat, or, better perhaps, from beer compared with wine,—a Demosthenes whose strength is rougher, and who has neither the flavour nor the sparkle.

Our best MSS. are the *Codex Crippsianus* and the *Codex Oxoniensis* (containing also Antiphon, Andocides, Isæus, Lycurgus). The three extant orations, with the fragment ascribed to Demades, ed. F. Blass, Lips. 1871. The fragments in Baier and Sauppe's *Oratores Attici*, vol. ii.

DINGWALL, a royal burgh of Scotland, the county town of Ross-shire, 15 miles north-west of Inverness, at the junction of the Sutherland and Dingwall and Skye railways. It occupies a low situation at the upper end of Cromarty Firth, where the valley of Strathpeffer unites with the alluvial lands at the mouth of the Conan. Though a neatly built and thriving place, it has nothing special to show except the curious old town-house, a few remains of the ancient mansion-house of the powerful family of Ross, and an obelisk 57 feet in height, erected to the memory of George, first earl of Cromarty. Dingwall, like so many towns on the same coast, is of Norse origin, and its name in Scandinavian signifies the Court Hill. In Gaelic it is known as Iubhir-pheoran, or the mouth of the Peffer. Its charter, granted by Alexander II., was renewed by James IV. It unites with Tain, Dornoch, Wick, Kirkwall, and Cromarty in returning one member to Parliament. Population in 1871, 2125.

DINKELSBÜHL, a town of Bavaria, in the department of Mittelfranken, or Middle Franconia, on the Wörnitz, about 40 miles by rail from Donauwörth, where the river joins the Danube. It is an important centre both of civil and ecclesiastical administration, and has a Roman catholic and a Protestant church, a Latin and

industrial school, and several benevolent institutions. The inhabitants carry on the manufacture of gloves, stockings, and other articles, and deal largely in cattle. Fortified by Henry I., Dinkelsbühl received in 1305 the same municipal rights as Ulm, and obtained in 1351 the position of a free imperial city, which it retained till 1803. Its municipal code, the *Dinkelsbühler Recht*, printed in 1536, and republished in a revised form in 1738, contained a very extensive collection of laws on matters both of public and private interest. Population in 1875, 5238.

DINOCRATES (called by Pliny Dinocrates), a Greek architect, who lived in the reign of Alexander the Great. He applied to that king's courtiers for an introduction to the Macedonian king, but was put off from time to time with vain promises. Impatient at the delay, he is said to have laid aside his usual dress, besmeared his body with oil in the manner of an athlete, thrown a lion's skin over his shoulders, and, with his head adorned with a wreath of palm branches, and a club in his hand, made his way through a dense crowd which surrounded the royal tribunal to the place where the king was dispensing justice. Amazed at the strange sight, Alexander asked him who he was. He replied that he had come into the royal presence to make known a scheme which would be worthy of the consideration of the greatest monarch in the world. Out of Mount Athos, a mountain rising like a pyramid to a height of 6780 feet topped with a cone of white limestone, he proposed to construct the gigantic figure of a man, holding a large city in his right hand, while in his left he held a gigantic tank large enough to contain all the water from the brooks in the peninsula. The story goes that the king was not displeased with the idea, but, as he thought it chimerical, it came to nothing. Alexander, however, was so delighted with the man, and with his bold and daring conceptions, that he carried Dinocrates with him when he went on his campaigns against Darius. He was employed by the king to design and lay out the city of Alexandria. This city was founded in 332 B.C., but the untimely death of Dinocrates prevented it from assuming the proportions intended by its designer. The Ephesians, whose temple of Diana had just been burnt down, employed him in its reconstruction. But perhaps the most original of all his conceptions was his design for a temple to Arsinoë, wife of Ptolemy II, king of Egypt. The roof of the building was to have been composed of a mass of loadstones, strong enough to hold floating in the air, and suspended within it, an iron statue of the queen.

DINORNIS (δειρός, terrible, and ὄρνις, bird), a genus of gigantic Struthious birds, believed to be extinct, which in post-Pliocene times must have formed a principal feature in the fauna of New Zealand. Their remains are found in greatest abundance in the provinces of Otago and Canterbury, often strewn in great profusion over the surface of the ground, but more usually met with buried in alluvial deposits, and in swamps; and they indicate that many of the species attained a huge size—thus the tibia of *Dinornis giganteus* measures about a yard in length, and the bird itself must have stood 10 or 11 feet high. Another species, *Dinornis elephantopus*, although less in height, possessed, according to Professor Owen, the most massive skeleton in the entire order of birds, its toe bones almost rivalling those of the elephant. Wing bones are believed to have been entirely wanting in those species which now constitute the genus *Dinornis*, as also the fourth toe, which is present along with rudimentary wing bones in the species which have been placed in the new genus *Palapteryx*. Among living birds *Dinornis* agrees most closely with the *Apteryx*, the diminutive living representative in New Zealand of this gigantic race of bipeds, while somewhat resembling the emu and cassowary in the formation of

the feathers. Judging from their general structure, and from the habits of their nearest living allies, these great wingless birds may be supposed to have inhabited the plains and hillsides rather than the forests of New Zealand, and to have been omnivorous, feeding indiscriminately on seeds and roots, lizards and insects. Crop-stones are often found in little heaps beside their skeletons, and as these are generally such stones as occur in the neighbourhood, it has been inferred that the *Dinornis* was comparatively stationary in its habits. New Zealand has been so thoroughly explored in recent years as to render it highly improbable that the moa, as the *Dinornis* is called by the Maoris, will yet be found alive, but there seems sufficient reason for believing that its final extinction may have taken place since the arrival of the Maori race in New Zealand. The Maoris have only been settled there for about five centuries, yet they have traditions regarding moa hunting, its bones are found in ancient cooking ovens, and many specimens have been obtained in which portions of the skin with feathers attached are still preserved. An egg has also been recently found containing the bones of the chick, and another measuring 10 inches long and 7 inches broad was taken from a grave, where it rested in the hands of a human skeleton. There is evidence of the coexistence in New Zealand of about 20 species of moas during post-Pliocene times, and this, as A. R. Wallace remarks, points to the conclusion that New Zealand was at one time a much more extensive land than it now is; while the fact, that recently remains of the *Dinornis* have been found in a post-Pliocene deposit in Queensland strengthens the supposition that when the moa flourished Australia and New Zealand formed portions of one continent.

DINOTHERIUM, an extinct mammal, fossil remains of which occur in the Miocene beds of France, Germany, Greece, and Northern India. These until lately consisted exclusively of teeth and the bones of the head. An entire skull, obtained from the Epplesheim beds of Hesse Darmstadt in 1836, measured $4\frac{1}{2}$ feet in length and 3 feet in breadth, and thus indicated an animal exceeding the elephant in size. Its upper jaw was destitute of incisor and canine teeth, but possessed 5 molars on each side, with a corresponding number in the jaw beneath. Its most remarkable feature, however, consisted in the front part of the lower jaw being bent downwards and bearing two tusk-like incisors also directed downwards and backwards. Judging from these remains Professor Owen placed the *Dinotherium* among the proboscidean mammals; De Blauville, on the other hand, regarded it as an aquatic animal, destitute of legs, and somewhat resembling the manatee,—its reversed tusks having probably been used to moor the creature to the bank of the streams it frequented, or to assist it in leaving the water. The recent discovery, however, of limb bones, decidedly proboscidean in type, and supposed to belong to the *Dinotherium*, supports the view that these creatures were more akin to the elephant and mastodon than to the manatee.

DIOCESE, from the Greek *διοίκησις*—primarily meaning administration, then the territorial circumscription in which administration was exercised—was first used to denote the Greek provinces of the Roman empire, or more properly the portion of a province ruled by a *propretor*. Thus Cicero had, besides Cilicia, three “dioceses” in Asia. Bingham (lib ix. c. 1) says that the division of the empire into clerical dioceses was in the time of Constantine, whereas the division into provinces was much anterior. He goes on to show that the primitive church followed exactly the example of the empire in her territorial arrangements. As in every metropolis of each province there was a magistrate with authority over the magistrates of each city, so in every metropolis there was a bishop, whose

authority extended over the entire province, who was thence called “metropolitan,” or “primate,” as being the first or principal bishop of the province. And everywhere the episcopal sees were under the authority of the bishop of the civil metropolis, except in Africa, where the primate was usually the senior bishop of the province. The term “diocese,” however, was sometimes used in the more comprehensive, and the term province in the less comprehensive sense, as appears from the *Notitia dignitatum Imperii*, drawn up, as it would seem, in the time of the emperors Arcadius and Honorius (see Bingham, *loc cit.*) The territorial division, however, as given in the *Notitia*, was purely civil. But Bingham tells us that, though we have no equally ancient account of the ecclesiastical division of the empire, yet if we compare the fragmentary bits of information which may be picked out of the acts of and subscriptions to the earlier councils with later notices, it will be seen that the ecclesiastical very exactly followed the civil distribution.

It may be mentioned that, before the 4th century, the term “parish”—*παροικία*—was often used indiscriminately with the word “diocese,” a circumstance which has caused ecclesiastical antiquarians to expend much erudition in showing that, despite the confusion of terms, the thing intended corresponded to our idea of a diocese, and not to our idea of a parish.

The uncertainty with regard to the number and circumscription of the English ecclesiastical dioceses under the Romans is great, and the information attainable fragmentary. At the council of Arles, held in the year 314, the bishop of York, the bishop of London, and the bishop “*de colonia Lindi*,” probably Lincoln, are recorded to have been present. But the changes in the number and territorial circumscription following the Saxon invasion—and not yet finally completed—were so great that volumes of minute antiquarian investigation would be needed to trace—in so far as it may be still possible to trace—the progress of nomenclature and delimitation of the various dioceses of Britain from the first establishment of them to the present day.

The division of dioceses found to be too large to be conveniently administered by one bishop was practised from very early times, as may be seen by the decrees of a council held in Portugal about the middle of the 6th century. Another reason for dividing a diocese, and establishing a new see, has been recognized by the church as duly existing “if the sovereign should think fit to endow some principal village or town with the rank and privileges of a city” (Bingham, lib. xvii. c. 5). But there are canons for the punishment of such as might induce the sovereign so to erect any town into a city, solely with the view of becoming bishop thereof. Nor could any diocese be divided without the consent of the primate.

In the countries more immediately subjected to the Roman pontiff the multiplication of dioceses has been excessive, the number of them in the apostolic dominions being no less than 68, while the Roman Church reckons in the whole of Europe (exclusive of the English, but inclusive of the Irish sees) 578 sees.

DIOCLETIAN. VALERIUS DIOCLETIANUS (245–313), Roman emperor, was born of obscure parents near Salona, in Dalmatia, and reigned from 284 to 305 A.D. He entered the army and served with high distinction, held important commands under the emperors Probus and Aurelian, and accompanied Carus to the Persian war. After the death of Numerianus he was chosen emperor by the troops at Chalcedon, and slew with his own hands Arrins Aper, the prefect of the prætorians. His advent to the throne marks the commencement of the era of Diocletian, August 29, 284. Having been installed at

Nicomedia, he received general acknowledgment after the murder of Carinus. He appointed Maximian Augustus in 286, and Constantius Chlorus and Galerius, Cæsars in 292. Each of the four rules was placed at a separate capital—Treves, Sirmium, Milan, Nicomedia. This amounted to an entirely new organization of the empire, on a plan commensurate with the work of government which it now had to effect. At the age of fifty-nine, exhausted with labour, he abdicated his sovereignty on May 1, 305, and retired to Salona, the place of his birth, where he died eight years afterwards. His reign was memorable for the persecution of the Christians.

DIODATI, GIOVANNI (1576–1649), a Swiss theologian of the Reformed Church, was born at Geneva on the 6th June 1576 of a noble family originally belonging to Lucca, which had been expatriated for the profession of Protestantism. In his youth he distinguished himself as a biblical scholar, and at the age of twenty-one he was nominated Professor of Hebrew at Geneva on the recommendation of Beza. In 1608 he became a pastor, or parish minister, at Geneva, and in the following year he succeeded Beza as professor of theology. As a preacher he was eloquent, bold, and fearless, with his full share of the intolerance that prevailed among his party at Geneva. He held a high place among the reformers of Geneva, by whom he was sent on a mission to France in 1614. He had previously visited Italy, and made the acquaintance of Sarpi and Fulgenzio, whom he endeavoured unsuccessfully to engage in a reformation movement. In 1618–19 he attended the Synod of Dort, and took a prominent part in its deliberations, being one of the six divines appointed to draw up the account of its proceedings. He was a thorough Calvinist, and entirely sympathized with the condemnation of the Arminians. In 1645 he resigned his professorship, and he died at Geneva on the 3d October 1649. Diodati is chiefly celebrated as the author of the translation of the Bible into Italian which appeared in 1603. Another edition with notes was issued in 1607. As a translator he possessed the primary qualification of a competent knowledge of the original, but his work was rather a paraphrase than a translation, and his notes were those of a theologian rather than of a critic. He also undertook a translation of the Bible into French, which appeared with notes in 1644. Among his other works were his *Annotationes in Biblia* (1607), of which an English translation was published in London in 1648, and various polemical treatises, such as *De fictitio Pontificiorum Purgatorio*, 1619; *De justa Secessione Reformatorum ab Ecclesia Romana*, 1628; *De Antichristo*, &c. He also published French translations of Sarpi's *History of the Council of Trent*, and of Edwin Sandys's *Account of the State of Religion in the West*.

DICODORUS, named SICULUS, a Greek historian, born at Agrinum in Sicily. Of his life we know nothing except what he himself has narrated, that, in prosecution of his historical researches, he undertook frequent and dangerous journeys, and studied Latin at Rome. His history occupied thirty years in writing, and was at last completed in forty books. From internal evidence it is certain that it was written after the death of Julius Cæsar; but the passages which show him to have survived the alteration of the calendar by Augustus are generally regarded as spurious. His history, to which, from its comprehensive plan, he has given the title of *Bibliotheca*, is divided into three parts. The first treats of the mythic history of the non-Hellenic, and afterwards of the Hellenic tribes; the second section ends with Alexander's death; and the third continues the history as far as the beginning of Cæsar's Gallic war. Of this extensive work there are still extant only the first five books, treating of the mythic history of the Egyptians,

Assyrians, Æthiopians, and Greeks; and also from the 11th to the 20th book inclusive, beginning with the second Persian war, and ending with the history of the successors of Alexander, previously to the partition of the Macedonian empire. The rest exists only in fragments which have been collected by Photius. The faults of Diodorus arise principally from the gigantic nature of the undertaking, the cumbrous nature of the materials, and the awkward form of annals into which he has thrown his narrative. He has been at little pains to sift his materials, and hence frequent repetitions and contradictions may be found in the body of the work. As a critic, he seems to have been altogether ignorant of the ethical advantages of history, and shrinks from administering praise or blame to the persons whose history he writes. In the chronology of the strictly historical period he is occasionally inaccurate, and the poetical myths which take the place of the early history are related with all the gravity of historical detail. His narrative is without colouring, and monotonous, and his simple and clear diction, which stands intermediate between pure Attic and the colloquial Greek of his time, enables us to detect in the narrative the undigested fragments of the materials which he employed. The particulars, however, which he has handed down are valuable, as enabling us in several points to rectify the errors of Livy.

The best editions of Diodorus are Wesseling's, 2 vols., Amstel 1745, that printed at Deux-Ponts, 11 vols., 1795–1801, Eichstadt's (to book xiv) 2 vols., Halle, 1802–4, and Dindorf's, 5 vols., Lips 1828–31.

DIODENES, of Apollonia in Crete, a celebrated natural philosopher who flourished at Athens about 460 B.C. He was a pupil of Anaximenes and a contemporary of Anaxagoras. The fragments of his writings have been collected together by Panzerbieter. He believed air to be the source of all being, and all other substances to be derived from it by condensation and rarefaction. His chief advance upon the doctrines of his master is that he asserted air, the primal force, to be intelligence—"the air which stirred within him not only prompted but instructed. The air as the origin of all things is necessarily an eternal, imperishable substance, but as soul it is also necessarily endowed with consciousness." Mr Lewes and Mr Grote assign to him a higher place in the evolution of philosophy than either Hegel or Schwegler.

DIODENES (about 412–223 B.C.), the famous Cynic philosopher, was the son of Icesias, a money-changer of Sinope in Pontus. Having been detected in adulterating coin, his father and he were compelled to leave their native city. According to another account, however, Icesias died in prison, and Diogenes fled to Athens with a single attendant. On his arrival in that city he dismissed his attendant with the piquant question, "If Manes could live without Diogenes, why not Diogenes without him?" and on the same principle he denuded himself of all superfluous dress, furniture, and even ideas. A wooden bowl, which, with his cloak and wallet, formed his only movables, is said to have been immediately discarded when he saw a boy drinking water from the hollow of his hand. The fame of Antisthenes soon attracted him to Cynosarges, and the pertinacity with which, for the sake of wisdom, he not only endured the scoffs but volunteered to submit to the blows of the great teacher, soon procured him a favourable reception from the whole Cynical school. The favourite pupil, however, soon outstripped his master in the extravagancies of his life, and the pungent keenness of his sarcasms. That he took up his abode in a cask belonging to the temple of Cybele is a circumstance liable to suspicion, from being more frequently alluded to by the satirists than by the biographers of Diogenes. That he

used to mure himself to the vicissitudes of the weather by rolling himself in hot sand in summer, and in winter by embracing statues covered with snow, are facts resting on the authority of all the ancient historians. His numerous witty apophthegms are preserved by Diogenes Laertius. After his voyage to Ægina, during which he fell into the hands of pirates, who sold him as a slave in Crete, the conduct of Diogenes appears in a much less ridiculous light. With characteristic boldness he proclaimed to his captors that he knew no trade except "to govern men," and wished to be sold "to a man that wanted a master." Such a purchaser he seems to have found in Xenias, who took him to Corinth to superintend the education of his children. There he spent the rest of his life, and he is said to have reached an extreme old age. There at the Isthmian games he taught the assembled concourse in the Kraneion; and thither he attracted a crowd of disciples when Antisthenes had ceased to tickle their ears in Cynosarges. There, too, in all probability, his famous interview with Alexander took place, in which the only favour he had to beg of the prince was that he would not stand between him and the sun,—when Alexander is said to have exclaimed, "If I were not Alexander, I would be Diogenes." To Athens Diogenes seems never to have returned. Of his death, which is said to have taken place on the same day with that of Alexander the Great, there are various conflicting accounts. That he perished by the bite of a dog, or from the immoderate use of raw flesh, or by his own hand, is now generally disbelieved. It is more probable that his death was calm and peaceful, and in spite of his desire to be thrown to the beasts of the field, he received from Xenias an honourable interment. In the days of Pausanias the Corinthians pointed with pride to his grave, and on the isthmus there was a pillar erected to his memory, on which, as the self-chosen symbol of his life, there rested a dog of Parian marble. His alleged connection with Laïs, and the open indecencies of which he is said to have been guilty, have thrown a shade upon his character. The former is, however, it must be confessed, exceedingly improbable, and the latter charge was undoubtedly exaggerated, if it was not originated by the shameless excesses of the later Cynics. The Cynics answered arguments by facts. When some one was arguing in support of Zeno of Elea's notion respecting the impossibility of movement, Diogenes rose and walked. Definitions might prove that there was no motion, but definitions were only verbal, and could be answered by facts. This appeal to common sense, the *argumentum ad bacillum*, was of more value and importance in ethical than in speculative philosophy.

DIODEGES LAERTIUS, the biographer of the Greek philosophers, is supposed by some to have received his surname from the town of Laerte in Cilicia, and by others from the Roman family of the Laertii. Of the circumstances of his life we know nothing. The date at which he wrote—probably the reign of Septimius Severus (193–211)—is known only from conjecture. His own opinions are equally uncertain. By some he was regarded as a Christian, but it seems more probable that he was an Epicurean. The work by which he is known professes to give an account of the lives and sayings of the Greek philosophers. Although it is at best an uncritical and unphilosophical compilation, its value, as giving us an insight into the private life of the Greek sages, justly led Montaigne to exclaim that he wished that instead of one Laertius there had been a dozen. In the commencement of the work he divides philosophers into the Ionic and Italic schools. The biographies of the former begin with Anaximander, and end with Clitomachus, Theophrastus, and Chrysippus, the latter begins with Pythagoras, and

ends with Epicurus. The Socratic school, with its various branches, is classed with the Ionic; while the Eleatics and sceptics are treated under the Italic. The whole of the last book is devoted to Epicurus. From the statements of Burleus, the text of Laertius seems to have been much fuller than that which we now possess; and hopes have been entertained of obtaining a more complete copy.

The best modern edition is that of Hubner, Leipsic, 2 vols 8vo, 1828–31.

DIOMEDES, son of the impetuous Tydeus, is a hero of the Ætolian and Argo-Theban legends. He is in the *Iliad* the leader of the tribes which belong to the government of the Amythionidæ. A favourite of Athene, from whom he received the gift of immortality, he does not spare even gods if she is standing by his side. He carried off the Trojan Palladium and brought it to Argos, where it was preserved by his descendants. He was known in many other places as a devotee of Athene and a supporter of her worship. In Argos his shield was carried through the town as a relic on the festival of Athene. A temple of Athene Anemotis (the storm ruler) was said to have been founded by him. He was worshipped in several parts of Italy, and in Salamis in Cyprus. Indeed he may be said generally to belong to the worship of Athene in so far as she is the goddess of storm and war.

DION, of Syracuse (408–353 B.C.), was the son of Hipparchus, and brother-in-law of Dionysius the Elder. In his youth he was an ardent admirer and diligent pupil of Plato, whom Dionysius had invited to Syracuse; and he used every effort to promote the carrying out of his master's maxims in the administration of the kingdom. His near relationship to the despot gave him great influence at court, and also enabled him to amass considerable wealth. Accordingly, on the accession of the younger Dionysius, the stern morality of the philosopher stood in marked contrast to the dissolute character of the prince. An antagonism thus silently sprung up between the two; and the proposal of Dion to invite Plato again to Syracuse was made the occasion of an open rupture. To counteract the influence of that distinguished philosopher, the enemies of Dion obtained the recall of the historian Philistus, who had already signalized himself as a faithful supporter of despotic power. This artful courtier quickly regained his ascendancy over the mind of Dionysius, and was at length successful in procuring the banishment of Dion. The exiled philosopher retired to Athens, where he was at first permitted to enjoy his revenues in peace; but the intercessions of Plato served to exasperate the tyrant, and at length provoked him to confiscate the property of Dion, and give his wife to another. This last outrage roused Dion to seek the liberation of his country by force of arms. Assembling a small force at Zacynthus, he sailed to Sicily, and, in the absence of Dionysius, was received with demonstrations of joy. He succeeded in defeating the forces of the tyrant, but was himself soon after supplanted by the intrigues of Heracles. Again he was banished, but the incompetency of the new leader soon led to his recall. He had, however, scarcely made himself master of Sicily when the people began to express their discontent with his tyrannical conduct, and he was assassinated by Calippus, an Athenian who had accompanied him in his expedition.

DION CASSIUS COCCEIANUS, the celebrated historian of Rome, was born at Nicæa in Bithynia, 155 A.D. His father's name was Cassius Apronianus, and by his mother's side he was the grandson of Dion Chrysostom, who also obtained the surname of Cocceianus. When a young man he accompanied his father to Cilicia, of which he had the administration, and on his father's death he went to Rome, where in the last year of the reign of Marcus Aurelius, or immediately after the death of that

emperor, he was received into the senate. During the reign of Commodus, Dion continued to practise as an advocate at the Roman bar, and held the offices of *ædile* and *quæstor*. He was raised to the prætorship by Pertinax, but did not assume office till the reign of Septimius Severus, with whom he was for a long time on the most intimate footing. By Macrinus he was intrusted with the administration of Pergamus and Smyrna, and on his return to Rome he was raised to the consulship about 220. After this he obtained the proconsulship of Africa, and again on his return was sent as legate successively to Dalmatia and Pannonia. He was raised a second time to the consulship by Alexander Severus, in 229, but under pretext of suffering from a diseased foot, he soon after retired to Nicæa, where he died. The date of his death is unknown. Previous to writing his history Dion Cassius had inscribed to the Emperor Severus an account of various dreams and prodigies which had presaged his elevation to the throne, and had also written a biography of the Emperor Commodus, which was afterwards incorporated into his larger work. The history of Rome, which consisted of 80 books,—and, after the example of Livy, was divided into decades,—began with the landing of *Æneas* in Italy, and was continued as far as the opening of the reign of Alexander Severus. The first 24 books exist only in fragments; from the 36th to the 54th, the work is extant complete; from the 55th to the 60th, it is probably an abridgment, and besides these, parts of the 71st and 75th books have also been recovered. The diligence of Dion as an historian is undoubted, and the various important offices which he held under the emperors gave him valuable opportunities for historical investigation. Although more philosophical than the compilations of the mere annalist, his work is not remarkable for vigour of judgment or critical acumen. His style is far clearer than that of Thucydides, whom he took as his model, but his diction is full of Latinisms.

His history was first published in a Latin translation by N. Leonicens, Venice, 1526. The best modern edition is that of Sturz, Leipzig, 1824–43, which contains the *Excerpta Vaticana*. Various other writings, such as a *History of Persia*, *Enodia* or *Itineraries*, a *Life of Arrian*, *Getica*, and a work on the Emperor Trajan, are attributed to Dion Cassius, but in all probability without foundation. The substance of his history is reproduced in the annals of Zouaras.

DION CHRYSOSTOM (*i.e.*, golden mouthed), (c. 50–117), was born at Prusa, in Bithynia, about the middle of the 1st century. He visited Egypt with his father at an early period of his life, and went to Rome during the reign of Domitian. Being implicated in a plot against the tyrant, Dion fled from the capital, and wandered about in Thrace, Mysia, Scythia, and the other countries of the *Getæ*, with only Plato's *Phædo* and Demosthenes *On the Embassy* in his possession, till the accession of Nerva, when he was allowed to return. With Nerva and Trajan he continued on the most friendly footing. He retired to Prusa for a short time; but having been accused of peculation and treason, he returned to Rome, where he remained till his death. Eighty orations of his are extant entire, and there are fragments of about fifteen others. They are written in a lucid and elegant style, and treat mostly of political, ethical, and mythological subjects.

DIONYSIA, or BACCHANALIA, were festivals in honour of DIONYSUS (*q.v.*) generally, but in particular the term refers to the festivals celebrated in Attica and by the branches of the Attic-Ionic race in the islands and in Asia Minor. In Attica there were two festivals annually. (1) The *lesser* Dionysia, or τὰ κατ' ἄρπυς, were held in the country places where the vine was grown in the month of December. This was a vintage festival, and was accompanied by songs, dance, phallus processions, and the unpromptu performances of itinerant players, who with others from the city thronged

to take part in the excitement of the rustic sports (2) The *greater* Dionysia, or τὰ ἐν ἄστυ, were held in the city of Athens in the month of March. This was a festival of joy at the departure of winter and the promise of summer, Dionysus being regarded as having delivered the people from the wants and troubles of winter. The religious act of the festival was the conveying of the ancient image of the god, which had been brought from Eleuthera to Athens, from the ancient sanctuary of the *Lenæon* to another sanctuary, with a chorus of boys and a procession carrying masks and singing the *dithyrambus*. The culmination of the festival was in the production of tragedies, comedies, and satiric dramas in the great theatre of Dionysus. Besides the Dionysia strictly so called, there were also the *Lenæa* and *Anthesteria*, both held in honour of this god, the former in January and the latter in February.

DIONYSIUS, the Elder (c. 430–367 B.C.), tyrant of Syracuse, was born about 430 B.C. He began life as a clerk in a public office, and first took part in political affairs during the dissensions that followed the destruction of the Athenian expedition. He was wounded in the attempt of Hermocrates to seize upon Syracuse, and, during the disasters inflicted by the Carthaginians who had invaded the island, he succeeded, along with Philistus and Hipparinus, in procuring the deposition of the Sicilian generals, and was himself included in the number appointed in their stead. By intriguing with the inhabitants of Gela, which he had been sent to relieve, and spreading insinuations of treachery in regard to his colleagues, he was ultimately invested with the supreme command; and by the help of a large body-guard he soon made himself independent of the popular opinion. Pestilence having thinned the Carthaginian army, Dionysius, in spite of his ill success, found no difficulty in procuring peace (405 B.C.) In the stronghold of Ortygia he defied the machinations of his enemies, until, partly from defeats and partly from dissensions, the opposition died away. After a successful expedition against Naxos, Catania, and Leontini, his efforts were directed against Carthage (See CARTHAGE). He also carried an expedition against Rhegium and its allied cities in Magna Græcia. In one campaign, in which he was joined by the Lucanians, he devastated the territories of Thurn, Croton, and Locri. After a protracted siege he took Rhegium, 387 B.C., and sold the inhabitants as slaves. He joined the Illyrians in an unsuccessful attempt to plunder the temple of Delphi, and also pillaged the temple of Cære on the Etruscan coast. In the Peloponnesian war he espoused the side of the Spartans. Not content with his military renown, Dionysius aspired also to poetical glory. His poems were hissed at the Olympic games; but having gained a prize for tragic poetry at Athens, he was so elated that he engaged in a debauch which proved fatal (367 B.C.) His life was written by Philistus, but the work has unfortunately perished.

DIONYSIUS, the Younger, ascended the throne of Syracuse at his father's death, in 367 B.C. He was driven from the kingdom by Dion, and fled to Locri, but during the commotions which followed the assassination of that leader, he managed to make himself master of Syracuse. On the arrival of Timoleon he was compelled to surrender and retire to Corinth (343 B.C.), where he spent the rest of his days in poverty.

DIONYSIUS, of Halicarnassus, was born about the middle of the first century B.C. His father's name was Alexander. From the introduction to his great work we learn that he went to Italy after the termination of the civil wars, and spent twenty-two years in preparing materials for his history, which is entitled *Archæologia*, and embraced the history of Rome from the mythical period

to the beginning of the first Punic war. It was divided into twenty books,—of which the first nine remain entire, the tenth and eleventh are nearly complete, and the remaining books only exist in fragments. In the first three books of Appian, and in the Camillus of Plutarch, much of Dionysius has undoubtedly been embodied. As an historian he is minute and painstaking; but his attempts to Grecianize the early history of Rome, that the Greeks might in some measure be reconciled to a foreign yoke, render his accuracy more than suspicious. Dionysius was also the author of a treatise on rhetoric, which, with his criticisms on Thucydides, Lysias, Isocrates, Isæus, Dinarchus, Plato, and Demosthenes, have been preserved. The best editions of his works are those of Hudson and Reiske. The rhetorical works have been edited separately, by Gros and by Westermann.

DIONYSIUS, the Areopagite, according to Suidas, was an Athenian by birth, and eminent for his literary attainments. He studied first at Athens, and afterwards at Heliopolis in Egypt. While in the latter city, he beheld that remarkable eclipse of the sun, as he terms it, which took place at the death of Christ, and exclaimed to his friend Apolophanes, ἢ τὸ θεῖον πάσχει, ἢ τὸ πᾶσιν συμπασχει. "Either the Divinity suffers, or sympathizes with some sufferer." He further details that, after Dionysius returned to Athens, he was admitted into the Areopagus, and, having embraced Christianity about 50 A.D., was constituted bishop of Athens by the apostle Paul (Acts xvii. 34). Aristides, an Athenian philosopher, asserts that he suffered martyrdom—a fact generally admitted by historians; but the precise period of his death, whether under Domitian, Trajan, or Adrian, is not certain. A writer in later times attempted to personate the Areopagite, and contrived to pass his productions on the Christian world as of the apostolic age, thereby greatly influencing the spirit of both the Eastern and Western Churches. These writings consist of a book called *The Celestial Hierarchy*; another *Of the Ecclesiastical Hierarchy: A Treatise on the Divine Names*; another *Of Mystical Divinity*; and *Ten Epistles*. Different opinions have been held as to the real author of these productions. They were ascribed, at an early period, to Apollinaris, bishop of Laodicea, in the 4th century. The resemblance between the *Areopagitica* and the writings of Proclus and Plotinus is so great that it is probable the Pseudo-Dionysius did not write much earlier than the 5th century. The first uncontroverted occasion on which these supposititious writings are referred to, is in the conference between the Severians (a sect of Eutychians) and the Catholics, held in the emperor Justinian's palace, 532 A.D., in which they are quoted by the heretical party.

DIONYSIUS, surnamed Periegetes, from his being the author of a περιήγησις τῆς γῆς, containing a description of the whole earth in hexameter verse, and written in a terse and elegant style. This work enjoyed a high degree of popularity in ancient times, and two translations or paraphrases of it were made by the Romans, one by Rufus Festus Avenius, and the other by the grammarian Priscian. The best edition of the original is that by Bernardy (Leipsic, 1828). Great differences of opinion have been entertained as to the age and country of this Dionysius. All, however, are agreed in placing him in the time of the Roman emperors, and it seems highly probable that he flourished in the latter part of the 3d or the beginning of the 4th century. Eustathius says that he was by descent a Libyan.

DIONYSIUS EXIGUUS, one of the most learned men of the 6th century, and especially distinguished as a chronologist, was, according to the statement of his friend Cassiodorus, a Scythian by birth, "*Scythæ natione*." This

may mean only that he was a native of the region bordering on the Black Sea, and does not necessarily imply that he was not of Greek origin. Such origin is indicated by his name and by his thorough familiarity with the Greek language. His surname "*Exiguus*" is usually translated "*the Little*," and is supposed to refer to his stature; but it appears to be at least as probable that his known humility led him to assume the designation. He was living at Rome in the first half of the 6th century, and is usually spoken of as abbot of a Roman monastery. Cassiodorus, however, calls him simply "*monk*," while Bede calls him "*abbot*." But as it was not unusual to apply the latter term to distinguished monks who were not heads of their houses, it is uncertain whether Dionysius was abbot in fact or only by courtesy. He was in high repute as a learned theologian, was profoundly versed in the Holy Scriptures and in canon law, and was also an accomplished mathematician and astronomer. We owe to him a collection of ecclesiastical canons, comprising the apostolical canons and the decrees of the councils of Niceæ, Constantinople, Chalcedon, and Sardis, and also a collection of the decretals of the Roman pontiffs from Siricius to Anastasius II. These collections were published by Justel in 1628. Dionysius did good service to his contemporaries by his translations of many Greek works into Latin; and by these translations some works, the originals of which have perished, have been handed down to us. His name, however, is now perhaps chiefly remembered for his chronological labours. It was Dionysius who introduced the method of reckoning the Christian era which we now use. (See *CHRONOLOGY*.) His friend Cassiodorus depicts in glowing terms the character of Dionysius as a saintly ascetic, and praises his wisdom and simplicity, his accomplishments and his lowly-mindedness, his power of eloquent speech and his capacity of silence. He died at Rome, probably about the year 545.

DIONYSUS, in Greek Mythology, is principally the god of the vine; and in the myths concerning him it is clear that the effects of wine and the spread of vine growing have both been kept in view. No sooner had the god grown up than he started on distant expeditions to teach men to cultivate the vine, and on these occasions his followers were known for their ecstatic ceremonies. It would seem also as if the story of his birth was only a mythical representation of the growth and ripening of the grape. Thebes in Bœotia was originally the local centre of his worship in Greece; and he was a son of Semele, a daughter of Cadmus, the king of Thebes, his father being Zeus, who among other divine functions exercised also that of god of the fertilizing spring showers. Before the child was mature, Zeus appeared to Semele at her request in his majesty as god of lightning, by which she was killed, but the infant was saved from the same fate by cool ivy which grew up suddenly around him. Zeus took him up, inclosed him within his own thigh till he came to maturity, and then brought him to the light, so that he was twice born; and it was to celebrate this double birth that the *dithyrambus* was sung. He was now conveyed by Hermes to be brought up by the nymphs of Nyssa, from which place it is probable his name Dionysus, or "*god of Nyssa*," is derived; but among the many places of this name claiming to have been the true one it is impossible to decide. In his journeys to teach the cultivation of the vine he met with opposition in some cases, as in that of Lycurgus, a Thracian king, from whose attack Dionysus saved himself by leaping into the sea, where he was kindly received by Thetis. Lycurgus was blinded by Zeus and soon died, or, according to another story, became frantic and hewed down his own son, mistaking him for a vine, while in a third story Ambrosia, who was changed

into a vine, clung so closely round him that, failing to escape, he died. A similar incident is that of Pentheus, king of Thebes, who opposed the orgiastic ceremonies introduced by Dionysus among the women of Thebes, and, having been present watching one of these ceremonies, was mistaken for some animal of the chase, pursued, and slain by his own mother. At Orchomenus, the three daughters of Minyas refused to join the other women in their nocturnal orgies, and for this were transformed into birds. It was in accordance with this tradition that in after times, at the festival of the *Agrionia*, the priests of Dionysus pursued the women of the race of Minyas with drawn swords, and if they captured them, killed them, which incident, it will be seen, also justifies the title of *ἄμνησις* applied to Dionysus. On the other hand, when the god was received hospitably he repaid the kindness by the gift of the vine, and of this the chief instance is that of Icarius of Attica, who lived in the time of King Pandion. But Icarius, instead of keeping secret the use of the vine, spread it among the herdsman and labourers, who, becoming intoxicated with the wine, slew him and threw him into a well or buried him under a tree, where his daughter Erigone found his grave, and in her despair hanged herself on the tree. In recollection of this it was the custom to hang small figures and masks on trees at the ceremony in her honour. The district of Icaria, though in Attica, was on the borders of Bœotia, which latter was the earliest and chief seat of the worship of Dionysus in Greece, with its famous festival on Mount Cithæron. Festivals of the same ecstatic kind spread to Attica, to Mount Parnassus, and north to Thrace. But in Bœotia Dionysus was personally associated with so many festivals and incidents that he has more the appearance of a hero or demigod than of a god, and it may have been from a sense of this that Herodotus (ii. 52) calls him the most recent of the gods. In Homer also he has a secondary character. To what extent the idea of his functions may have been derived from the Vedic god Soma cannot be determined, but the similarity between the two deities becomes the more striking when we remember how actively the worship of Dionysus was conducted in Asia Minor, particularly in Phrygia and Lydia, where he was styled Sabazius, with the epithet also of *βασιλεὺς*, from which it is supposed his Greek name of Bacchos was derived. As Sabazius he was associated with the Phrygian goddess Cybele, and was followed in his expeditions by a *thiasos* of Centaurs, Pan, Satyrs, and Silenus. In Lydia his triumphant return from India was celebrated by an annual festival on Mount Tmolus, and it was in Lydia that he assumed the long beard and long robe which were afterwards given him in his character as the "Indian Bacchus." The other incidents in which he appears in a purely triumphal character are his transforming the Tyrrhene pirates who attacked him into dolphins, as told in the Homeric hymn to Dionysus, and as represented on the monument of Lysicrates at Athens, and his part in the war of the gods against the giants. The adventure with the pirates occurred on his voyage to Naxos, where he found Ariadne when she had been abandoned by Theseus. At Naxos Ariadne was associated with Dionysus as his wife, and their marriage was annually celebrated by a festival (See *ARIADNE*.) Another phase in the myth of Dionysus originated in observing the decay of vegetation in winter, to suit which he was supposed to be slain and to join the deities of the lower world, in which connection he figured in the mysteries of Eleusis. This phase of his character was developed by the Orphic poets, he having here the name of Zagreus, and being no longer the Theban god, but a son of Zeus and Persephone. The child was brought up secretly, watched over by Kuretes, but the jealous Hera discovered where he was, and sent Titans to

the spot, who, finding him at play, tore him to pieces, and cooked and ate his limbs, while Hera gave his heart to Zeus. To connect this with the myth of the Theban birth of Dionysus, it is said that Zeus gave the child's heart to Semele, or himself swallowed it and gave birth to the Theban god. Altogether there were, it was said, five different gods "Dionysus," each having different parentage. The conception of Zagreus, or the winter Dionysus, appears to have originated in Crete, but it was accepted also in Delphi, where his grave was shown, at which sacrifice was secretly offered annually on the shortest day. This feature of going away in the winter and returning at spring, which was common to Dionysus and Apollo, would commend the former god to the priests of Apollo at Delphi. Dionysus had further, in common with Apollo, the prophetic gift. Like Hermes, he was a god of the productivity of nature, and hence Priapus was one of his regular companions, while not only in the mysteries but in the rural festivals his symbol, the phallus, was carried about ostentatiously. His symbols from the animal kingdom were the bull, panther, ass, and goat. His personal attributes are an ivy wreath, the thyrsus (a staff with pine cone at the end), a drinking cup (*cantharus*), and sometimes the horn of a bull on his forehead. Artistically he was represented mostly either as a youth of soft nearly feminine form, or as a bearded and draped man, but frequently also as an infant, with reference to his birth or to his bringing up in Nysa. The earliest images were of wood with the branches still attached in parts, whence he was called Dionysus Dendrites. He was figured also, like Hermes, in the form of a pillar or term surmounted by his head.

The Greek colonists of Southern Italy (Magna Græcia) had taken with them the worship of Dionysus, and so successfully had it spread there that Sophocles (*Antig.* 1106) speaks of him as the god who rules in Italy. From Campania the joint worship of Dionysus (Liber), Demeter (Ceres), and Kore (Libera) was introduced into Rome, and a temple was erected to them 495 B.C., in obedience to the Sibylline books. But the mysteries which were held in connection with this worship were suppressed by the senate, 186 B.C. In Campania Dionysus was styled Hebon, and conceived in the form of a bull with a human head. Libera, usually identified with Kore, corresponds rather to the goddess Hebe as worshipped at Phlius. (A. S. M.)

DIOPHANTUS. See *ALGEBRA*, vol. i. p. 511.

DIPHThERIA (from *διφθέρω*, a skin or membrane), the term applied to an acute infectious disease, which is accompanied by a membranous exudation on a mucous surface, generally on the tonsils and back of the throat or pharynx. Although popularly believed to be a newly discovered disease, there is distinct evidence that diphtheria was known to the ancient physicians as a malady of great virulence. Under the name of the *Malum Egyptiacum*, Aretæus in the 2d century gives a minute description of a disease which in all its essential characteristics corresponds to diphtheria. In the 16th, 17th, and 18th centuries epidemics of diphtheria appear to have frequently prevailed in many parts of Europe, particularly in Holland, Spain, Italy, France, as well as in England, and were described by physicians belonging to those countries under various titles, but it is probable that other diseases of a similar nature were included in their descriptions, and no accurate account of this affection had been published till M. Bretonneau of Tours in 1821 laid his celebrated treatise on the subject before the French Academy of Medicine. By him the term *Le Diphthérie* was first given to the disease. The subject has since been largely investigated both in Britain and on the Continent, where epidemics more or less extensive have been of common occurrence in recent times; but while many important facts have been made out

regarding the pathology of diphtheria, the real nature of the malady still appears to be undetermined. By some it is regarded as primarily a blood poison, the local manifestations being secondary and not essential, while others hold, and this is the view now largely maintained by Continental authorities, that diphtheria is at first a local disease, the constitution becoming secondarily affected or poisoned from the local affection. This latter view receives support both from experiments on inoculation of the disease in animals, and from the discovery in the diphtheritic membranes and surrounding tissues, as well as in the blood and other fluids of persons suffering from diphtheria, of the lower forms of vegetable organism (bacteria, micrococci, &c.), which are supposed to be the infecting agents both in the local affection and in its general constitutional effects. Whether this be the correct explanation of the disease, or whether as is held by many, these organisms are to be looked upon merely as accompaniments or complications of the affection, not present in all cases, the following facts appear to be made out respecting diphtheria —

1 That it is a disease communicable both by infection and by contagion

2 That grave constitutional disturbance is a constant and prominent symptom of diphtheria.

3 That certain important consequences or, as they are termed, sequelæ are apt to follow diphtheria, particularly some forms of paralysis.

These points, moreover, serve to distinguish this disease from croup, which, although in some cases presenting certain features of resemblance to diphtheria, differs from it in being a merely local inflammatory affection. See GROUP.

As already observed, diphtheria has frequently appeared as an epidemic. It is probably more common in a sporadic form (single cases). It is sometimes endemic in certain localities where the hygienic conditions are bad; and there is ample evidence to show that air or water contaminated with decomposing animal matter may readily cause an outbreak of diphtheria. The influence of climate, weather, and condition of soil appear to be inappreciable. When the disease has broken out in a dwelling it is apt to spread not merely by direct contagion, but apparently also through the air of apartments, this being notably the case in overcrowded habitations. The contagiousness of diphtheria is very marked, and has unhappily been often exemplified in the case of physicians, who have fallen victims to the disease from inoculation with its morbid products when canterizing the throats or performing tracheotomy in those suffering from it. Children appear to be on the whole rather more liable to diphtheria than adults, and although the most robust people may be attacked, those whose health is weakened by any cause are specially predisposed. One attack of diphtheria appears to afford no immunity from others.

It must be observed, however, that the mere existence of a sore throat accompanied with some amount of membranous exudation does not constitute diphtheria, as is often erroneously supposed by non-medical persons, who are apt to fancy they have had diphtheria several times from having suffered from what is a comparatively simple complaint. The diagnosis can only be reliably made by a medical man.

Cases of diphtheria differ as to their intensity from the mildest forms, which resemble an ordinary catarrhal sore throat, to those of the most severe character (such as the gangrenous form), where the disease is hopelessly intractable from the first.

In general the symptoms at the commencement of an attack of diphtheria are comparatively slight, being those commonly accompanying a cold, viz, chilliness and depression. Sometimes more severe phenomena usher in the attack, such as vomiting and diarrhœa. A slight feeling of

uneasiness in the throat is experienced along with some stiffness of the back of the neck. When looked at the throat appears reddened and somewhat swollen, particularly in the neighbourhood of the tonsils, the soft palate, and upper part of pharynx, while along with this there is tenderness and swelling of the glands at the angles of the jaws. The affection of the throat spreads rapidly, and soon the characteristic exudation appears on the inflamed surface in the form of greyish-white specks or patches, increasing in extent and thickness until a yellowish-looking false membrane is formed. This deposit is firmly adherent to the mucous membrane beneath or incorporated with it, and if removed leaves a raw, bleeding, ulcerated surface, upon which it is reproduced in a short period. The appearance of the exudation has been compared to wet parchment or washed leather, and it is more or less dense in texture. It may cover the whole of the back of the throat, the cavity of the mouth, and the posterior nares, and spread downwards into the air passages on the one hand and into the alimentary canal on the other, while any wound on the surface of the body is liable to become covered with it. This membrane is apt to be detached spontaneously, and as it loosens it becomes decomposed, giving a most offensive and characteristic odour to the breath. There is pain and difficulty in swallowing, but unless the disease has affected the larynx no affection of the breathing. The voice acquires a suffling character. When the disease invades the posterior nares an ærid, fetid discharge, and sometimes also copious bleeding, takes place from the nostrils. Along with these local phenomena there is evidence of constitutional disturbance of the most severe character. There may be no great amount of fever, but there is marked depression and loss of strength. The pulse becomes small and frequent, the countenance pale, the swelling of the glands of the neck increases, which, along with the presence of albumen in the urine, testifies to a condition of blood poisoning. Unless favourable symptoms emerge death takes place within three or four days or sooner, either from the rapid extension of the false membrane into the air passage, giving rise to asphyxia, or from a condition of general collapse, which is sometimes remarkably sudden. In cases of recovery the change for the better is marked by an arrest in the extension of the false membrane, the detachment and expectoration of that already formed, and the healing of the ulcerated mucous membrane beneath. Along with this there is a general improvement in the symptoms, the power of swallowing returns, and the strength gradually increases, while the glandular enlargement of the neck diminishes, and the albumen disappears from the urine. Recovery, however, is generally slow, and it is many weeks before full convalescence is established. Even, however, where diphtheria ends thus favourably, the peculiar sequelæ already mentioned are apt to follow, generally within a period of two or three weeks after all the local evidence of the disease has disappeared. These secondary affections may occur after mild as well as after severe attacks, and they are principally in the form of paralysis affecting the soft palate and pharynx, causing difficulty in swallowing with regurgitation of food through the nose, and giving a peculiar nasal character to the voice. There are, however, other forms of paralysis occurring after diphtheria, especially that effecting the muscles of the eye, which produces a loss of the power of accommodation and consequent impairment of vision. There may be, besides, paralysis of both legs, and occasionally also of one side of the body (hemiplegia). These symptoms, however, after continuing for a variable length of time, almost always ultimately disappear.

In the treatment of diphtheria regard must be had both

to the local and general nature of the disease. Difference of opinion exists among physicians as to the utility of topical applications in the form of caustics applied to the affected parts, some attaching great importance to their use as tending to arrest the progress of the disease, while others hold that the irritation so produced favours the spread of the false membranes. Probably at the outset, when the local manifestations are but slight, the use of such a caustic as nitrate of silver, either in the solid form or in strong solution, may be of service; but after any considerable surface has been invaded by the false membrane little good, it is to be feared, can be done in this way. The forcible removal of the false membrane is generally condemned, as by this means a raw bleeding surface is left, upon which the deposit is reproduced with great rapidity. The oxidation, however, tends to be cast off spontaneously by a process of suppuration, and, as favouring this, and at the same time acting as a soothing remedy, the inhalation of steam is recommended. The employment, in the form of spray or of washes or gargles, of solutions of carbolic acid, Condy's fluid, perchloride of iron, chlorine water, or chlorate of potash, is valuable in the way of disinfecting the parts, and subduing the fetid exhalations which are always present. When the disease has spread into the larynx and the breathing is embarrassed, an emetic may be of use in aiding the expulsion of the false membrane. It is, however, in great measure to the constitutional treatment that the physician's attention must be directed in diphtheria. The effect of the disease upon the patient's strength is so marked that from the very beginning there is an urgent demand for strong nourishment, which should be freely administered in the form of milk, soup, &c., as long as there exists the power of swallowing, and when this fails nutrient enemata should be resorted to. Large doses of quinine and of the tincture of the perchloride of iron are recommended, and stimulants will in almost all cases be called for from an early period. The question of tracheotomy has to be considered when the false membrane has spread into the air passages and threatens death by asphyxia; and although the operation in such circumstances affords but a feeble chance of success, the cases of recovery by this means have been sufficiently numerous to justify its employment as a last resort. The paralysis which follows diphtheria usually yields in the course of time to tonics and good nourishment.

It should be mentioned that in all cases of diphtheria means should be taken by isolation of the patient and the use of disinfectants to prevent as far as possible the spread of the disease in a household; while the attendants ought to be scrupulously careful to avoid inoculation with the products of the disease, and should frequently use gargles of some of those substances above mentioned. (J O A)

DIPLOMACY is the art of conducting the intercourse of nations with each other. The word obviously owes its origin to the source subsequently explained in the article **DIPLOMATICS**. It is singular that a term of so much practical importance in politics and history should be so recent in its adoption that it is not to be found in Johnson's dictionary. There has, indeed, ever been a reluctance in the English nature to acknowledge the art of transacting international business as a pursuit worthy of a British statesman, or as one cutting its adepts to honourable fame. It is popularly looked on as the art of carrying into the business of nations a morality condemned in the intercourse of men with each other, and as a means of employing subtlety where force is insufficient to accomplish some statesman's object. Hence the term has been colloquially used to express a modified degree of cunning, and conduct which is wily and subtle, without being directly false or fraudulent, is styled "diplomatic."

The subject has been usually treated under the head of the Law of Nations, or, as it is now more properly termed, international law. But a little examination will show that diplomacy, though closely associated with international law, is a separate sphere of intellectual exertion. The diplomatist undoubtedly requires to be acquainted with international law, and to observe its general injunctions. He often finds it necessary to appeal to the rules, or supposed rules, of that code, but it would be a confusion of terms to count him an officer engaged in the execution of international law. He has to accomplish objects which are not achievable through any law real or fictitious, but are achieved solely through the art of diplomacy. Questions in which private rights and obligations are concerned are a perpetual source of diplomatic exertion. In England, and to some extent in the other states called the great powers, the administration of justice is pursued on rules so absolute that there is no chance of their being relinquished to favour a friendly or to injure a hostile nation. Further, diplomacy, besides the larger operations connected with great treaties or alliances, keeps a vigilant eye on the ordinary details of international law, for the purpose of seeing that it is equitably administered. In this sense the diplomatist is like a law-agent, whose duty it is to see that his client receives justice at the hands of other nations under this code.

Diplomacy, as a science, has arisen out of the development of the European powers, and their rise on the ruins of the Roman empire. As a uniform system, following principles nearly as well established as those of many codes of law, it exists solely among the European powers, partly embracing those nations, such as Turkey and Persia, which have been brought into close association with them. The difficulty, however, of getting those Eastern states to understand and obey the laws of diplomacy, and submit to its restraints, has ever been an object of anxious comment to Wickefort and the other systematic writers on diplomacy. To submit to be bound in the moment of power by a theoretical system not enforced by the strong hand of any judge, spiritual or temporal, is not consistent with the Oriental mind, and the great civilized powers, in dealing with the Eastern states, as in their intercourse with barbarous tribes, have relied on their own strength, exercised with cruelty or with mildness as the case might be. Alliances and leagues, declarations of war and treaties of peace, have taken place, it is true, among those states, but it would be an historical absurdity to suppose diplomatic relations connecting together China, Birmah, and Japan, as they connect the great European powers.

In the same manner the ancient world had its treaties and leagues, but no systematic diplomatic relations. The pretensions of Rome during the empire, indeed, superseded every kind of international engagement, since she would permit of no relation between the empire and any other state, save that of predominance on her part and subjection on the other. Yet it is evidently from this system of centralization that the diplomatic relations of the European states arose. Freed from the temporal jurisdiction of the empire, and no longer mere dependencies, the European states were still subject in a modified shape to an influence radiating from the old centre of imperial authority. The bishop of Rome, in claiming a spiritual authority at least co-extensive with the geographical area of the temporal authority of the departed emperors of Rome, created a sanction, though an imperfect one, for the execution of justice among nations, and acted in some measure as a controlling influence over their diplomatic operations. A memorable instance of the influence of the Pope is found in the relations between John of England and Philip of France. The semi-judicial authority of the court of

Rome was cited in support of the English conquest of Ireland, and was appealed to by both parties in the Scottish War of Independence. Little as the Papal authority was respected by even the most Catholic monarchs when they were at the head of large and well-found armies, yet in matters of dubious equilibrium the authority of the Pope had some weight; and as his was a power not limited to any particular state or cluster of states, but ever present throughout all the transactions of Christian realms with each other, it had, beyond doubt, an influence gradual and continuous in giving modern diplomacy the amount of specific character which it had obtained at the period of the Reformation. Under the head **BALANCE OF POWER**, the evils arising from the absence of a supreme power to judge between states, as the courts of law decide questions between individual citizens, will be found discussed. It suffices here to say, that much of the deficiency is filled up by the fortunate train of events which have created, throughout the civilized world, a traditional system of diplomatic practice.

The representatives of great nations, following up the traditions of the science of diplomacy, have often sought by similar acts to do what they considered their duty to their country by taking advantage of every opportunity of aggrandizing it. But modern political philosophy and morality teach us that this is not the manner in which great nations are to be supported or aggrandized, and that for their diplomatic servants there is spread out a far nobler field of exertion. It is founded on the consciousness that the real power of states must come from within—from the sound condition of the people, physically, industrially, and morally—from well-poised political institutions and good government. If these are absent no diplomatic skill can make up for them, if they be present it cannot enhance the real power of the state which possesses them. But to the diplomatic representatives of states both powerful and honest a function of a higher character still than mere national aggrandizement belongs, in the capacity, by able, temperate, and honourable negotiation, to keep feeble states from being crushed by their potent neighbours, to preserve peace in the world so long as it can honourably be preserved, and to see generally that international justice is observed among mankind. The true functions of the great powers are in some measure embodied in the well-known lines of Virgil:

*"Tu regere imperio populos, Romane, memento,
Hæ tibi erunt artes, pacisque imponere morem,
Parcere subjectis, et debellare superbos."*

The historical events, and the industrial and commercial progress which have during the past hundred years so aggrandized the power of Britain among European nations, have, in this view of the uses of our diplomacy, become a great boon to the smaller states, and even to the citizens of the greater. The parliamentary responsibility, and the perpetual public scrutiny and discussion to which the acts of our statesmen are subjected, are not only checks on our own diplomatic acts, but on those of every other civilized state. It was a boast attributed to one of the great fabricators of British diplomacy, the elder Pitt, that not a gun should be fired throughout the world without Britain knowing why. If Britain could make good this boast, it would extend in some measure to mankind at large the blessings enjoyed at home from living under a responsible government. As it is even at present, the continuous liability of having whatever he does called before Parliament and the public, must be an ever present and influencing motive with every British diplomatist. Hence he not only dare not countenance any act of national rapacity, tyranny, or fraud, but he is, as the representative of a nation which has great power and no secrets, a check upon the diplomatic honesty of all the world.

In contrast to the old opinions which attributed the power and prosperity of nations to diplomatic ability, overlooking the substantial sources of material progress, a political sect has appeared in recent times who denounce the diplomatic system as foolish or wicked, and proclaim the doctrine of non-intervention in the affairs of other nations. It is practically clear, however, that whatever degree of perfection the world may reach in time, the first great power which avows this opinion will become the immediate victim of its rivals; and thus, should Britain withdraw herself from the diplomacy of Europe, the despotic states would soon become strong enough to shunt up the commerce of the world, and cast the world two centuries back in civilization.

It is perhaps scarcely necessary to mention that the source of the diplomatic organization in any nation is its supreme power; but it is useful to keep in view that, for the rapid movements of this department of politics, nations the most jealous of their constitutional rights have been obliged to place at least provisional power in the hands of individual rulers. Thus in Britain the sovereign, independently of Parliament, has technically the power to make treaties and to declare peace and war; and an authority not much less extensive is committed to the president of the United States. The guidance of a great state's relations with foreign countries is generally committed to one department of the Government—with us it is the function of the foreign secretary. How far he is bound to consult his colleagues in his intercourse with foreign states has sometimes been matter of acrimonious discussion. The representatives of the Government at foreign courts, though the dignified character of their missions sometimes gives them a rank much higher than that of their instructor, must obey the directions of the foreign minister. In the negotiation of treaties there is an old-standing dispute among publicists, how far nations can be bound if their ambassadors exceed the instructions given to them, which are generally kept secret. When, therefore, an important international act, such as a treaty, is undertaken, there are many sanctions and ceremonials to be accomplished before it is held to be completed. While matters are in a vague condition, many briefly expressed fundamental suggestions will have passed among the negotiators in the form of notes. When the matter becomes more ripe for adjustment, it assumes the shape of a protocol, or draft of the conditions. The ambassadors, when all is adjusted, sign the articles of the treaty; but still it is generally deemed essential that the several Governments should ratify it, or, admitting that their representatives have not exceeded their instructions, engage to fulfil the bargain they have made. In this country, whenever treaties affect the private rights of the citizen, they must be ratified by Act of Parliament. In addition to notes and substantive treaties, the most important documents in diplomacy may be considered the manifestoes, in which, paying homage to public opinion and the established rules of diplomacy, Governments profess to justify their conduct. When any vile act of oppression or injustice is perpetrated, it is generally followed by an able manifesto, and the ingenuity of the accomplished diplomatist is taxed to make the deed appear just, rational, and necessary.

The nature and functions of the large body of officers who chiefly conduct the diplomacy of the world having been described under the heading **AMBASSADOR**, it only remains to notice the incidental circumstance that custom has for some time established the French language as the language of diplomacy. In the 16th and during a great part of the 17th century, Latin was employed. In Ludlow's memoirs there is, under the year 1656, a curious notice to the effect that the Swedish ambassador "com-

plained of the delays in his business, and that, when he desired to have the articles of this treaty put into Latin according to the custom of treaties, it was fourteen days they made him stay for that translation, and sent it to *one Mr Mitox, a blind man*, to put them into Latin, who, he said must use an amanuensis to read it to him, and that amanuensis might publish the matter of the articles as he pleased, and that it seemed strange to him there should be none but a blind man capable of putting a few articles into Latin." In turning over the pages of the great collection of treaties by Dumont and Rousset, one may observe how gradually, during the ascendancy of Richelieu, and the subsequent reign of Louis XIV, the use of the French language radiates from the immediate diplomatic transactions of France over those of Europe at large. Probably its propagation was originally connected with the visions of that universal French empire to which Louis XIV. seemed to be marvelling before he encountered the combinations of William of Orange. At the present day it can only be pronounced a fortunate thing that diplomatists have agreed to use one language, and that the best adapted for their peculiar functions.

DIPLOMATICS, the science derived from the study of ancient diplomas, so called from being written on two leaves, or on double tablets. The Romans used the term more specially for the letters of licence to use the public conveyances provided at the different stations, and generally for public grants. Subsequently it attained a more extended signification, and in more modern times has been used as a general term for ancient imperial and ecclesiastical acts and grants, public treaties, deeds of conveyance, letters, wills, and similar instruments, drawn up in forms and marked with peculiarities varying with their dates and countries. With the revival of literature, the importance of such documents in verifying facts and establishing public and private rights led to their being brought together from the historical works and the monastic registers in which they had been copied, or, in rarer instances, from public and ecclesiastical archives where the originals were still preserved. Then arose questions of authenticity, and doubts of the so-called originals, disputants defended or condemned them; and, in order to establish principles for distinguishing the genuine from the forged, treatises were written on the whole subject of these diplomas. With a view to establish the credit of those preserved in the original, the Benedictine, Dom Mabillon, in the year 1681 produced his masterly work *De re diplomatica*,—Papebroech, the Jesuit, having already, in the year 1675, written his *Proprium antiquarum circa veri ac falsi discrimen in vetustis membranis* in the *Acta Sanctorum*, April, vol. ii. In the following century appeared the *Nouveau Traité de Diplomatique*, by Dom Toustain (who, however, died before the completion of the work) and Dom Tassin, Benedictines of the congregation of St Maur, 6 vols. 4to, 1750–1765, treating of the whole subject of diplomas, and accordingly entering at length into a minute investigation of the peculiarities and characteristics of writing proper to different ages and countries. Thus treatises on the subject of diplomas gave the name of diplomatics to the study of ancient writing, now more properly termed PALEOGRAPHY, under which it will be separately treated.

Imperial decrees and privileges, public acts and treaties, and, no doubt, contracts between private persons, were in remote times inscribed on marble and stone, on wood and on metal. The wonderfully preserved monuments of ancient Nineveh show the prevalent use of sun-burnt brick. In Egypt papyrus was used from the remotest times. The Greeks and Romans recorded public documents on wooden tablets, on stone, bronze, lead, and ivory, as well as on papyrus, parchment, and other sub-

stances. Tablets of wax served for letters and writings of various kinds, but must have been unsuitable for public acts. Pliny speaks of the use of rolls of lead and of linen. There are many Greek documents preserved in the British Museum, the Bibliothèque Nationale of Paris, and elsewhere, such as royal letters, petitions, contracts, and wills, of the time of the Ptolemies, written on papyrus. See *Notices et Extraits des Manuscrits*, tome xviii, with plates. The Byzantine emperors often used golden and coloured inks from the 8th to the 12th century.

We know that archives were provided by the Romans for the preservation of their public acts, but fire and war have been the great destroyers of these documents so precious to the historian. Suetonius relates that Vespasian undertook to restore from copies 3000 brazen tablets, containing most ancient records, dating almost from the beginning of the republic, which had been consumed when the Capitol was burnt. Original documents of the nature of diplomas, written in Latin, are now not forthcoming of an earlier period than the 5th century. The acts emanating from royal authority anterior to the 13th century are almost exclusively derived from ecclesiastical archives, and consist of foundations of monasteries, and grants of property, privileges, and immunities. In England, from the 13th century they are systematically registered in the royal chancery, the series of rolls in which they are written, under different classes, is very complete from the reign of King John. History is greatly indebted to the care with which religious houses registered their title deeds. From an early time it was their practice to copy them into volumes, arranging them generally under the name of the property. Chartularies of this character of the 10th century are still extant. The chartulary of Winchester Abbey, compiled early in the 12th century, and containing numerous documents of the time before the Conquest, is in the British Museum.

Imperial acts affecting the state at large were proclaimed through the governors of provinces; as in later times, in England royal writs and ordinances were addressed to the sheriffs of the several counties. In England, it would seem, when the object was to appeal to the people, the document was publicly exhibited. When Edward III. landed, as Prince of Wales, on the Yorkshire coast, with the design of overthrowing his father's government, he drew up a manifesto of his purposes, addressed to the citizens of London, who exhibited it on the cross in the Cheap, placing copies in their windows (*Chron. Monasterii de Melsa*.)

At all times diplomas have been drawn very much in set forms. The Romans employed official clerks, (*scribæ*), assigning them to the different magistrates. Under the empire they are called *tabelliones*, and act as public notaries. After the breaking up of the Roman empire, there was a period when the chanceries of the new states were imperfectly served. The notarial science was partially lost, and, in the general neglect of learning, the composing a public act or private document was a task of difficulty. In the 7th century the monk Marculfus composed a formulary for guidance in drawing up documents of various kinds. It was first published by Bignon in 1613. In Migne's edition, *Patrologiæ Cursus*, vol. xxxvii, it is accompanied with several anonymous compilations of the same character. In the 12th and 13th centuries we meet with works of the same kind under the title of *de arte dictaminum*. A very interesting collection of precedents of royal warrants, state letters, papal bulls, and other documents, arranged under many heads of subjects, was compiled by the English poet Occleve, while he was a clerk in the council office at the beginning of the 15th century, and is now in the British Museum. We are best able to understand the nature of

early diplomas by examining the originals, still extant, on papyrus or parchment, which go back in date to the 5th century. The oldest come chiefly from Ravenna. They have been commented on by Maffei in his *Istoria diplomatica*, 1727, and printed in full with facsimiles in the *Papiri diplomatici* of the Abbate Marino-Marini, 1805. A considerable number of the original diplomas of the Merovingian and succeeding sovereigns of France have also been preserved, and have been published in facsimile (Letronne, *Diplomata et Chartæ*), and in letterpress. England also can boast of a series of very beautifully written royal charters from the 7th century. The larger number of them are in the British Museum, and are in course of publication in facsimile (*Facsimiles of Ancient Charters*, parts I. II. III.) Many original papal bulls, too, of an early date, are still extant, in different repositories.

There is a general uniformity in the diplomas of the earlier times. Taking the French series as examples, we find a regularity of formulas in the following order—

1. An invocation, as *In nomine domini Dei Salvatoris nostri Jesu Christi*

2. The name and style of the sovereign, and the name and title of the person addressed. In the 6th, 7th, and 8th centuries, the style of the French kings was in general *N. Francorum rex, vir illustris*; Pepin added *Dei Gratia*. From the time of Louis le Débonnaire the form was *Divina ordinante (or propitiante, annuente, or favente) providentia (clementia, or misericordia)*. Popes called themselves simply bishop until the end of the 11th century, when, or only rarely before, they used the title *Papa*. Gregory the Great (590-604) introduced the form *servus servorum Dei*. They placed their name before or after that of the person addressed indifferently, before the 10th century, when the custom prevailed to give it precedence.

3. A preamble, consisting of a moral or religious reflexion, or a recital of the motives to the grant. In the earlier times the moral sentiment is expressed briefly, as *Memor finis mei*, or *Pœnas inferni cupiens effugere*, but later on it is often of great length and in inflated language, with admixture of barbarized Greek words.

4. The substance of the act or donation.

5. A protecting clause, in the nature of an imprecation on such as should infringe the privilege granted, or thwart the object of the act. It is first met with in papal bulls of the 6th century, and appears in an exaggerated form in a later time, the bitterest curses being heaped on the hypothetical offender without measure. The papal type is closely followed in French and English diplomas. In the 12th century it took a milder form, as in papal bulls, *Nulli ergo hominum liceat*, &c. In the 10th and 11th centuries the comminatory clause was often placed after the date, having sometimes been previously introduced into the text.

6. The Merovingian sovereigns authenticated their diplomas by the addition of their signature. Those who were unable to write signed with their monogram. The Carolingians signed with a monogram, and the same form prevailed from the 9th century in Germany and Italy. It ceased to be used in France in the 14th century. The clergy adopted the use of the monogram in the 11th and 12th centuries. It is not found in the charters of English sovereigns. In the earlier times the monogram was formed of letters of tall cursive character, capitals and uncials were afterwards more commonly used. Sometimes the word *rex* was added. It is possible that the monogram was in some instances entered by the hand of the sovereign, for so much is indicated by the words in which it is introduced, but it was usually added by the chancellor or scribe. It was not used for some kinds of documents, as judgments, decrees, and mandates. In acts of the later Roman emperor, the form of subscription is simply the word *Legi*, with a cross prefixed, as in a diploma of Valentinian, printed by Marini, p. 94. The name of the referendary or chancellor, with the expression *optulit*, was in France, in the earliest time, inserted before, subsequently after, the subscription of the monarch. A paraph of the word *subscript*, and often Roman notes, accompanied the subscriptions. Sometimes in royal diplomas, and commonly in private charters, the names of several witnesses were subscribed, each preceded by the word *signum*, with a cross, or followed by *subscript*. The popes, in their bulls, originally used the form of *Bene valete*, or *Deus te incolumem seruet*, in place of subscription of their name, which they applied only to synodal and other public acts. At the beginning of the 9th century they used their monogram. In the 14th century they signed with their own hand. In the 9th century also began the practice of adding the subscriptions of cardinals, but it was not commonly followed until the middle of the 12th century. Sentences from the Scriptures were used by popes for a

signature, instead of their names, in consistorial bulls in the 11th century. English kings, before the Conquest, neither signed their name nor used a monogram. They affixed the sign of the cross—the scribe adding *Signum manus N. regis*, or variations of the form.

7. Dating clause. In France, this followed the subscription and attestation. The manner of dating varied at different times, and in different countries. In diplomas of the emperors, the year is not expressed. For example, an act of Valentinian of about 480 A.D. has simply the words, *Dat. sexto idus Januarii, Ravennæ + Legi*. The Merovingian kings and their successors dated by their regnal years, adding the day of the month, the place, and generally the word *felicitate*. Some dated from epochs in their reign, as Louis le Débonnaire from Easter 781, the day of his coronation at Rome, from September 813, when he was associated in the imperial power, and from the 28th of January 814, the day of his accession after the death of Charlemagne.

The year of the incarnation was seldom used by the French kings before the end of the 9th century. In England it was generally added to royal charters in the times preceding the Conquest, but, subsequently to the death of William the Conqueror, was very rarely used in public or private deeds until the 13th century. The English charters of the early period often added also the regnal year and papal indiction. In papal bulls the date was given by the names of consuls from 385 to 546, by years of the Greek emperors from 550 to 772; by years of emperors of the west from 802 to 1047, and in 1111, and by years of the pontificate as early as the year 781, but often still by the year of the emperor, or by both together, eventually by the year of the pontificate alone. The year of the incarnation is found in bulls as early as the 7th century, and came into ordinary use in 968. Up to 1088, in the papal dominions, the year was calculated from the 25th of December; subsequently the Florentine and Pisan years were used, the former beginning three months after the nativity, the other nine months before it. The indiction was also added—from 584 to 1087, that of Constantinople, beginning on the 1st of September, afterwards the Constantinian, or Cæsarean, beginning on the 25th of September, and the Papal, beginning on the 1st of January. These dates were accumulated principally in the bulls, in the briefs the year is rarely designated from 1086 to 1124, and is always wanting from 1124 to 1187. (See Jaffé, *Regesta Pontificum Romanorum*.)

An additional security was given to diplomas by the seal,—the antiquity (going back to remotest ages), the form, colour, substance, and use of which are treated of at great length in works on diplomatics (see SEALS). It was in use by the popes from the earliest time, and under the Merovingian kings and their successors, but by the great feudatories only from the 10th century. In England it is not found during the Saxon period, saving in a few instances in the reign of Edward the Confessor. The use of it came in with the Conquest and became general. The popes' seals were of lead, or in rare instances of gold, and suspended to the document. The precious material was introduced by Charlemagne, and was freely employed by the emperors of Constantinople, who with their principal officers used metal seals. In France, under the Merovingians, and elsewhere at the same period, the seal was of white wax, fixed "en placard," or to the surface of the document. From the 10th century, it was suspended, first by a parchment label, afterwards by cords of silk or other substances. The colour of the cords by which papal bullæ were attached varies under different pontiffs. White wax, but of various qualities, was in use to the 13th century, in which and subsequently it was coloured chiefly yellow, red, or green. The quality of the wax, the shape, the legend or inscription, the character of the charge or device—which was sometimes the impression of an antique gem—all these change with the progress of time and become evidence of age.

English charters of the Saxon period have forms in many respects different from those of foreign diplomas. Variations have been already noticed, as, that the king signed neither with his name nor with his monogram, but only with a cross, and that they were dated from the incarnation. It would appear, indeed, that the charters were not drawn up by an officer of the chancery, as in France, but were composed and written by ecclesiastics, whose services were employed for the occasion. In the grant of the monastery of Reculver to Christ Church, Canterbury, by King Eadred, in the year 949, to which Dunstan, then abbot of Glastonbury, and one of the king's principal ministers is a witness, he states that he both drew up the form and wrote the document with his own hand. It is on this account that we find in English charters before the Conquest a variety of styles of writing, even in those of the same date; whereas on the Continent the writing is uniform in the several states. In the absence of a strictly official character, the grant was attested by numerous witnesses, varying from four or five, the more ordinary number in the earlier times, to from 30 to 100 subsequently. For it was always an object with the religious houses in whose favour a grant was made to fortify its authority and secure its recognition by impressive solemnities. They made the benefaction a religious act by inviting the grantor to offer the charter to God on the altar of their church; and they obtained the approval and attestations of the members of the court, or of the council over which the king might be at the time presiding. The names which are subscribed to the English charters add greatly to their historical value. A difference in another respect from the foreign type is attended with advantage to the study of both the language and manners of the time. The property conveyed was defined by a minute description of its boundaries, written in English; and, as the documents are dated and can generally be referred to special localities, dialectic differences and the formation of names, with other incidental lights on subjects of antiquity, are preserved. In English charters of as early a date as the 9th century, and from that time onwards, is sometimes found, at the top or the bottom, the upper or lower half of an inscription. It is often the word *chirographum*, but sometimes other words, or merely letters. It was used when it was an object that two parties to a contract should each have a copy of the deed, which accordingly was written in duplicate on one skin, the inscription was written in large letters between the copies, and the skin was then divided. The line of division was at a later period generally indented, and the document was called an indenture. The custom was not introduced into France until the middle of the 11th century.

The practice of forging and falsifying diplomas, ecclesiastical constitutions, and documents of all kinds is traced back to very early times. The laws of the Visigoths of the 7th century enact severe punishments on offenders of this class, as do the *Capitularia* of Charlemagne. The English chronicler Hoveden, under the year 1196, gives an account of wholesale forgeries of papal bulls and briefs by an agent of the archbishop of York. A decretal of Innocent III. (1195-1216) gives rules for detecting fabricated bulls (*Epist.* i. 201, ed Baluz). It was so easy to impose upon the ignorance of people, and the temptations to falsify were so great, that we cannot doubt it was done extensively. The science of diplomatics professes to give the power to detect these forgeries. The two concluding books of the *Nouveau Traité de Diplomatique* treat of the subject at great length, but the rules given for distinguishing the true from the false document can only be applied by one who is practically versed in the study. In passing judgment on a professed original,

not only the formulas, historical facts, and date have to be tested, but the external features have to be regarded—the material, the ink, the forms of abbreviation and character of writing, and the seal; and the properties and characteristics of these cannot well be learnt from written instruction. They are treated of in works on the general subject of palæography.

In testing the authenticity of diplomas, assistances will be found, in addition to authors already quoted, in the following works:—Germon (Barthélemy), *De veteribus regum Francorum diplomatis*, Paris 1703-1707, 3 vols. 12mo; Muratori, *De diplomatis et chartis antiquis*, *Antiquit Ital medii ævi*, tom iii; Raguet, *Hist. des contestations sur la diplomatique*, 12mo, 1708, and 8vo, 1767; Hickes, *De antiquæ litteraturæ septentrionalis utilitate dissertatio epistolaris*, fol Oxon 1703, Marino-Marini, *Diplomatica pontificia*, 4to, 1841, Kemble, *Codex Diplomaticus ævi Anglosaxonici*, 6 vols 8vo, 1839-1848; Quantin, *Dictionnaire raisonné de Diplomatique Chrétienne*, in Migne's *Encyclopédie Théologique*, 1846; *Archives de l'Empire, Monuments Historiques, Cartons des Rois*, ed. J. Tardif, Paris, 4to 1866, *Bibliothèque de l'Ecole des Chartes*, 1839-1875, Gloria, *Compendio di Palæografia e Diplomatica*, 8vo, 1870 (E. A. B.)

DIPPEL, JOHANN CONRAD (1673-1734), a German theologian and alchemist, who assumed as an author the name "Christianus Democritus," was born at the castle of Frankenstein, near Darmstadt, his father being a Lutheran clergyman. He studied at Giessen, where he took the degree of master in philosophy in 1693. After a short visit to Wittenberg he went to Strasburg, where he delivered lectures on astrology and chiromancy, and occasionally preached. He gained considerable popularity, but was obliged after a time to quit the city, owing to his irregular manner of living, and the suspicion attaching to him of having been concerned in a murder. He had up to this time espoused the cause of the orthodox as against the pietists, and had justified his gay and worldly habits on the ground that he intended to make a practical protest against pietism; but in his two first published works, *Orthodoxia Orthodoxorum* (1697) and *Papismus vapulans Protestantium* (1698), he assailed vehemently the fundamental positions of the Lutheran theology, denying the inspiration of Scripture, the efficacy of the sacraments, and the doctrine of justification by faith. He held that religion consisted not in dogma but exclusively in love and self-sacrifice. To avoid persecution he was compelled to wander from place to place, and he resided successively in various towns of Germany, Holland, Denmark, and Sweden. He took the degree of doctor of medicine at Leyden in 1711. From 1698 he devoted himself to experiments in alchemy, which wasted a considerable fortune, and he was frequently imprisoned for debt. He made several valuable discoveries in chemistry, one being Prussian blue and another an oil, still known as Dippel's animal oil, which he offered as a panacea, and which has useful medicinal properties of a more limited kind. Provoked by false reports of his death, he published in 1733 an intimation that he would live until 1808. In spite of this, however, he died at Berleburg on the 25th April 1734.

An enlarged edition of Dippel's collected works was published at Berleburg in 1743. See a somewhat too eulogistic biography by Ackermann (Leipsic, 1781), and a memoir by Büchner in the *Historisches Taschenbuch* for 1858.

DIPSOMANIA. See MENTAL DISEASES

DIPTERA (Aristotle, from *δι*, double, and *πτερά*, wings), an Order of the *Insecta*, containing the "flies," properly so called, with which, also, in spite of not possessing its chief characteristic, the sub-order *Aphaniptera* (fleas), a part of the obsolete *Aptera*, is now incorporated. The *Diptera* proper (with the exception of the apterous *Nycteribudæ*, and a few aberrant species of other families, to which the majority of the characters given will not strictly apply, but which cannot, from their general structure, meta-

morphoses, habits, or evident natural affinities, be separated from the Order under consideration) have the following characters—wings two, mesothoracic, membranous, mostly horizontal and transparent, not capable of being folded, with nervures generally few and longitudinally disposed, and having a pair of alnlets at the base; metathoracic wings replaced by a pair of halteres or balancers; mouth antliate (whence the Fabrician name *Antliata* for the Order), with a proboscis formed of the labium, inclosing modifications of other usual parts of the mouth, except of the labial palpi, which are wanting, tarsi 5-jointed, prothorax reduced to a very small collar. They are divided into two sections—the *ORTHORHAPHA*, in which the pupa is incomplete (the details of the future perfect insect being visible), and the *CYCLORHAPHA*, in which the pupa is coarctate (of a hard, uniform surface, cylindrical, rounded at the extremities). The *ORTHORHAPHA* are again divided into two sub-sections—the *Nematocera* (antennæ composed of more than 6 joints, palpi 4- or 5-jointed), and the *Brachycera* (antennæ short, with apparently only three distinct joints, palpi 1- or 2-jointed). Of these, the *Nematocera* comprise three tribes, viz.—1, the *Oligoneura*, in which the wings have very few nerves (fam. *Cecidomyiidae*), 2, the *Eucephala*, in which the larva has a distinct head (fams. *Mycetophilidae*, *Bibionidae*, *Rhyphidae*, *Simuliidae*, *Chironomidae*, *Culicidae*, and *Psychodidae*); and 3, the *Polyneura*, in which the wings have many veins (fam. *Tipulidae*). The *Brachycera* also comprise three tribes, viz.—1, the *Cyclocera*, in which the third joint of the antennæ is annulated (divided into two groups—*a*, *Notacantha*, = fams. *Stratiomyiidae*, *Xylophagidae*, and *Acanthomeridae*; and *b*, *Tanytoma*, = fams. *Tabanidae* and *Leptidae*), 2, the *Orthocera*, in which the antennæ are normal (divided into two groups—*c*, *Polytoma*, = fams. *Therevidae* and *Scenopinidae*; and *d*, *Procephala*, = fams. *Acroceridae*, *Bombyliidae*, *Nemestrinidae*, *Mydasidae*, *Asilidae*, *Empidae*, and *Dolichopodidae*); and 3, the *Acroptera*, in which the wings are pointed (fam. *Lonchopidae*). The *CYCLORHAPHA* in like manner are divided into two sub-sections—the *Proboscidea*, possessing a proboscis, and the larvæ having an œsophageal frame, and the *Eproboscidea* (also variously termed *Coriacea* or *Pupipara*), in which the proboscis is wanting, the body leathery, and the larvæ have no œsophageal frame. Of these, the *Proboscidea* comprise three tribes, viz.—1, the *Hypocera*, in which the antennæ are inserted quite close to the mouth (fam. *Phoridae*); 2, the *Pseudoneura*, in which the wings have a false longitudinal veinlet (fam. *Syrphidae*), and 3, the *Eumyidae*, or type flies (fams. *Pipunculidae*, *Platypezidae*, *Conopidae*, *Muscidae*, and *Estridae*). The *Eproboscidea* comprise three families, all parasitic,—the *Hippoboscidae*, *Nycteribidae*, and *Streblidae*, the latter a very limited and aberrant group stated to be oviparous, and having the wings distinct and well veined, unlike the *Nycteribidae*.

The sub-order *Aphanoptera* consists of two families only, the *Pulicidae* and *Platyphylidae* (the latter so peculiar in structure as to have been claimed for the *Coleoptera*). Its members are parasitic, entirely coriaceous, much compressed or flattened, and destitute of wings or balancers, these organs being represented by more or less obsolete leathery plates; they have 3- or 4-jointed antennæ, 4-jointed maxillary and 3-jointed labial palpi, and 5-jointed tarsi. The larvæ of such of them as are known are vermiform, and the pupæ inactive, incomplete. If not considered as a sub-order, these two families would apparently have to be placed at the head of the Eucephalous *Nematocera*,—in that case, of course, deranging the characters given for that tribe.

Other families of the *Diptera* have been proposed, but

need not be here noticed, being as yet scarcely established, or merely entitled to the rank of sub-families (the *Muscidae* especially comprising many of the latter).

The *Diptera*, in number of species and individuals (very many having swarming propensities), have been considered to be the order of animated beings most diffused over the globe; and the extremes of heat and cold seem alike indifferent to them. They have long been known to abound in very high latitudes; and, among the insects brought back by Captain Feilden, the naturalist attached to Sir George Narces's Arctic expedition, were Dipterous species of apparently the most feeble organism. The Rev. A. E. Eaton, attached as naturalist to the late "Transit of Venus" expedition, discovered also, on the desolate shores of Kerguelen's Island, *Diptera* of a degraded type suitable to the climatic peculiarities of the locality. Tropical countries naturally furnish the most developed and in some cases extraordinary forms,—the genera *Pangonia*, *Rhopalomeria*, *Achias*, *Diopsis*, and *Elaphomyia*, and various *Acroceridae* (even in temperate regions) abounding in instances of exaggerated and apparently unnatural structure. To a geographical distribution of the widest extent, the flies add a range of habits of the most diversified nature, they are both animal and vegetable feeders, an enormous number of their species acting as scavengers in consuming putrescent or decomposing matter of both kinds. The phytophagous species are attached to various parts of the plant, dead or alive; and the carnivorous in like manner feed on dead or living flesh, many being parasitic on living animals of various classes (even *Reptilia*, as a fly is parasitic upon frogs in Australia), and more especially upon other insects, including *Hymenoptera*, of which they frequently simulate the external facies. No reasonable approximation can be made to the number of existing species, as the *Diptera* are not collected or examined with the same assiduity as the more attractive orders. Schiner, however, in 1868, stated the number then recorded to be no less than 20,800, to which a considerable annual increase is being made (*eg*, 550 species in 1869, and 230 in 1875); and more than 4000 different genera have been found necessary for their reception. These must be nevertheless taken as vastly below the mark of existent species. No catalogue of the British species has recently been made; Westwood, in 1840, enumerated about 2350.

Considered in relation to man, there would seem to be sufficient reason for placing this apparently feeble order at the head of our insect enemies. Allowing for the good effected by the clearing away of animal and vegetable impurities by many species, and for the indirect advantage caused by the known instances of a few others assisting in the fecundation of plants, there remains a long list of direct injuries effected by *Diptera*. Without laying undue stress upon the formation of galls and other vegetable deteriorations caused by many species, there can be no doubt that the destruction of grass-lands by the larva of the crane-fly, or "Daddy Long-Legs" (*Tipula oleracea*), of olive-crops by *Dacus*, of oranges by *Ceratitus*, of various culinary plants by *Pesla*, *Tephritis*, *Anthomyia*, *Phytomyza*, *Drosophila*, &c., and of wheat and other crops by the "Hessian fly," *Oscinis*, and *Chlorops*, are of very serious consequence. Our domestic animals, moreover, suffer from the bot-flies (*Estrus*, *Gasterophilus*, and *Cephenemyia*), the tick (*Melophagus*), gad-flies (*Tabanus*, *Hæmatopota*, *Chrysops*, and *Stomoxys*, many of which attack man himself), and last, and most dreaded, the African "Zimb," or "Tsetse," *Glossina morsitans*, which is of sufficient power to close the exploration of a region in which it occurs. Nor is man himself spared; the petty inconveniences of wasted food, broken rest, and slight personal

pain or irritation experienced in temperate regions from fly-larvæ, gnats, midges, &c., and the parasitic species, are aggravated in both warmer and more boreal countries to a dangerous extent, and have even been found prejudicial to life. There are many recorded instances of the larvæ of *Diptera* feeding upon the human intestinal canal, and of species (dubiously referred to *Estrus*) attacking man; as also of loathsome cases of individuals being eaten alive by the larvæ of flies, developed in food secreted about the persons of beggars. Various cases have, moreover, recently been noted of the diffusion of the germs of disease by flies; and instances of death from transference of putrid animal matter in New Caledonia have also been recorded. One of the *Muscidæ*, *Lucilia hominivorax*, is known to have caused considerable destruction to human life among French convicts in Cayenne, laying its eggs in the mouth or nostrils during sleep, and a very precise account of much disease and death in man and domestic animals at Mohilew, by a similar action of another of the same family, *Sarcophila wohlfarti*, has recently been given by Portchinsky, a Russian naturalist. It is perhaps superfluous to speak of mosquitoes, too well known since the Biblical "plague of flies;" but it may be observed that the corresponding plague of sand-flies, *Simulium*, so well known to affect the eyes of sufferers from ophthalmia in Egypt, has made its appearance in the deserts of West Australia, where the last exploring expedition of Mr Ernest Giles suffered severely from it.

The antiquity of the fly is scarcely more than historical. Very few fossil species are known (5 only being recorded from the Solenhofen lithographic Oolite), but the more recent "flies in amber" are so constantly found that the expression has become a common proverb. (E. C. R.)

DIPTYCH, a double tablet made with a hinge to open and shut. Diptychs were used in the time of the Roman empire for sending letters—"mainly love letters," says Facciolati, quoting the scholiast to Juvenal ix. 36, whose note does not, however, seem to imply as much. The consuls and questors used, on assuming office, to send diptychs containing their names and portraits to their friends. The exterior of the leaves was often ornamented with other paintings. The tablets were made, the more ordinary kind of boxwood or maple, the richer sort of cedar, of ivory, of silver, and sometimes even of gold. They were very frequently sent by friends to each other as presents at the beginning of a new year. The early Christians used tablets thus made in the celebration of divine worship. And Cardinal Noris (*Dissertat. de Hist. Synod.*) expends much learning in showing, what is very evident, that the Christians adopted the use of them from that of the consular diptychs. They were placed on the "ambones,"—the pulpits, or-reading desks, which may still be seen in ancient basilicas at the west end of the choir or presbytery; and from them were read to the congregation of the faithful the names of the celebrating priests, of those who occupied the superior positions in the Christian hierarchy, of the saints, martyrs, and confessors, and, in process of time, also of those who had died in the faith. It is the diptychs that are referred to by the early Christian writers under the names of "mystic tablets," "anniversary books," "matriculation registers" of the church, and sometimes "books of the living," or "books of life." The word is also occasionally found used in other senses, e.g. for the priest's vestment, which was usually folded in two (see Ducange, *ad voc.*) When it became customary to write in the diptychs names so numerous as those of the different classes of persons above mentioned, it will be easily understood that it became impossible to inscribe them on two tablets of convenient size. Hence the diptychs became triptychs, i.e., consisting of three such conjoined tablets.

But, though triptychs are often spoken of in the art-language of a later time, these were by the early church writers still called diptychs; and continued to be so-called, even when many leaves, probably of parchment in some cases, though more frequently of wood, were introduced between the two original folds of the diptych, thus forming a veritable book. The inscription on the diptychs of deaths and baptisms, naturally led to the insertion of dates, and the diptychs seem thus to have grown into calendars, and to have been the germ from which necrologies, lists of saints, and almanacs have been developed. Much doubt exists as to the time when the use of diptychs to read from died out in the church. The best opinion seems to be that their use lasted to about the end of the 8th century. The outsides of the diptych folds being often very richly ornamented, their preservation was carefully attended to, and even those which were ornamented with profane paintings or carvings were often to be found in use in the primitive churches. This ornamentation caused the diptychs to be exhibited to the congregation, and used as adornments for the altar. And in this position, by a natural process of development, the ornamentation became the main end and object of the thing itself. The best painters of the time employed their talents in painting them—generally in the form of triptychs, and on both sides of the folding doors, so that the triptych when closed showed two subjects, often the portraits of the donor and his wife, and when open three paintings,—hence the very large number of diptychs and triptychs which are found in our museums and galleries.

See Bingham, *Orig. Eccles.*, lib. xv. ch. 13, sec. 18, and Moroni, *Erudizione Storica-Ecclesiastica*.

DIRCE, in Greek legend, the personification of a fountain (and stream) at Thebes, from the water of which Hercules derived part of his strength, and which was usually identified with the fountain of Ares in the legend of Cadmus. Besides, the fountain was the grave of Dirce, at which sacrifices for the dead and other rites were performed. According to the legend, Dirce, the wife of Lycus, king of Thebes, had sorely persecuted Antiope, who at last escaped to Mount Cithæron, where her twin sons Amphion and Zethus were being brought up by a herdsman unconscious of their parentage. Mother and sons met, but had not recognized each other, till Dirce, who had come to the hill for a Dionysiac ceremony, proposed that Amphion and Zethus should tie Antiope to the horns of a wild bull to be dragged to death. They were about to do this when the herdsman announced their relationship, and they then tied Dirce to the bull instead. She was dragged by it over the hill to the fountain into which she was transformed.

DIRSCHAU, in Polish *Szczawo*, a town of Prussia, in the government of Dantzic and district of Stargard, on the left bank of the Vistula, at a railway junction about twenty miles S S E. of Dantzic. Besides dealing in wood and cattle, it displays considerable industrial activity in the manufacture of agricultural implements, iron and tin wares, and cement; but its principal claim to attention is the lattice-work iron bridge, thrown across the river in 1850–1857, which, with its total length of 2726 feet and its six spans of 410 feet each, is a noble testimony to the engineering skill of Lentze and Schinz, and affords a passage for the railway between Königsberg and Berlin, for two ordinary carriage roads, and two sideways for foot passengers. Unfortunately, as it lies only about 12 feet above the highest level attained by the river, and there is no opening for the passage of ships, it is necessary in passing under it to remove or drop the masts. J. Forster, the traveller, was born at Dirschau in 1729. Population in 1875, 9727.

DISCUS, a quoit, or circular plate of stone or metal, 10 or 12 inches in diameter, which was used by the ancient Greeks and Romans for throwing to a distance as a gymnastic exercise. Sometimes a kind of quoit of a spherical form was used for the same purpose; and through a hole in its centre a thong was passed, to assist the player in throwing it. Statius, in *Theb.*, vi. 646–721, fully explains the manner in which the discus was used. In the British Museum there is a copy of a famous statue by Myron of a discobolus in the act of throwing the discus.

DISINFECTANTS are agents or substances employed to prevent the spread of contagious or infectious disease. Recent investigations all tend to demonstrate that the efficiency of any disinfectant is due to its power of destroying, or of rendering inert, specific poisons or disease germs which possess in themselves an independent existence, and which, when introduced into the animal system, under favourable conditions, increase and multiply, thus producing the phenomena of special diseases. Therefore, antiseptic substances generally, which check or stop putrefactive decay in organic compounds, by preventing the growth of those minute organisms which produce putrefaction, are, on that account, disinfectants. So also the deodorizers, which act by oxidizing or otherwise changing the chemical constitution of volatile substances disseminated in the air, or which prevent noxious exhalations from organic substances, are in virtue of these properties effective disinfectants in certain diseases. A knowledge of the value of disinfectants, and the use of some of the most valuable agents, can be traced to very remote times; and much of the Levitical law of cleansing, as well as the origin of numerous heathen ceremonial practices, are clearly based on a perception of the value of disinfection. The means of disinfection, and the substances employed, are very numerous, as are the classes and conditions of disease and contagion they are designed to meet. Nature, in the oxidizing influence of freely circulating atmospheric air, in the purifying effect of water, and in the powerful deodorizing properties of common earth, has provided the most potent ever-present and acting disinfecting media. Of the artificial disinfectants employed or available three classes may be recognized:—1st, volatile or vaporizable substances, which attack impurities in the air; 2d, chemical agents for acting on the diseased body or on the infectious discharges therefrom; and 3d, the physical agencies of heat and cold. In some of these cases the destruction of the contagium is effected by the formation of new chemical compounds by oxidation, deoxidation, or other reaction, and in others the conditions favourable to life are removed or life is destroyed by high temperature. Of the first class—aerial disinfectants—those most employed are the gaseous sulphurous anhydride, the fumes of nitrous acid and other acid substances, including vaporized carbolic acid, with chlorine gas and the vapours of bromine and iodine. The use of sulphurous anhydride, obtained by burning sulphur, is of great antiquity, and it still is unequalled as a disinfectant of air on account both of its convenience and general efficacy. Camphor and some volatile oils have also been employed as air disinfectants, but their virtues lie chiefly in masking, not destroying, noxious effluvia. In the 2d class—non-gaseous disinfecting compounds—all the numerous antiseptic substances may be reckoned; but the substances principally employed in practice are oxidizing agents, as potassic manganates and permanganates (Condy's fluid), and solutions of the so-called chlorides of lime, soda, and potash, with the chlorides of aluminium and zinc, soluble sulphates and sulphites, solutions of sulphurous acid, and the tar products—carbolic, cresylic, and salicylic acids. Dr J. Dongall of Glasgow found the following substances the most powerful in destroying minute forms of

life—sulphate of copper, chloride of aluminium, chromic acid and bichromate of potassium, bichloride of mercury, benzoic acid, bromal hydrate, chloral hydrate, hydrocyanic acid, alum, hydrochlorate of strychnia, ferrous sulphate, arsenious acid, and picric acid. Of the physical agents heat and cold, the latter, though a powerful natural disinfectant, is not practically available by artificial means, heat is a power chiefly relied on for purifying and disinfecting clothes, bedding, and textile substances generally. Different degrees of temperature are required for the destruction of the virus of various diseases; but as clothing, &c, can be exposed to a heat of about 250° Fahr. without injury, provision is made for submitting articles to nearly that temperature. For the thorough disinfection of a sick-room the employment of all three classes of disinfectants, for purifying the air, for destroying the virus at its point of origin, and for cleansing clothing, &c, may be required.

DISLOCATION. This term is applied in surgery to the displacement from each other of the cartilaginous or articular surfaces of the bones entering into the formation of a joint. In a normal joint these surfaces are in contact and held together by ligaments and muscles, in a dislocated joint they are separated more or less completely—in the great majority of cases by external violence; in some instances, however, by powerful muscular exertion. The ease with which a joint is dislocated varies with the form and structure of the joint and with the position in which the joint is when the force is applied. The relative frequency of fracture and dislocation depends on the strength of the bones above and below the joint relatively to the strength of the joint. These points may be illustrated by examples from the joints of the arm and leg, because, with perhaps the exception of the joint between the lower jaw and the skull, it is in these situations that dislocation is most frequently observed. The strength of the different joints in the body is dependent on either ligament, muscle, or the shape of the bones. In the hip, for instance, all three sources of strength are present; therefore, considering the great leverage of the long thigh bone, the hip is rarely dislocated. The shoulder, in order to allow of extensive movement, has no osseous or ligamentous strength; its strength is muscular, therefore it is frequently dislocated, because the muscular strength varies in power, the muscles may be relaxed, the person is unprepared, and dislocation occurs; if, on the other hand, the muscles are tense, and the patient is prepared for the strain, then the result will be either a sprain of the joint or a fracture of one of the adjoining bones. The wrist and ankle are rarely dislocated, in the wrist the radius gives way, in the ankle the fibula, these bones being relatively weaker than the respective joints. The wrist owes its strength to ligament, the ankle to the shape of the bones. The elbow is osseously strong, but this strength necessarily varies with the position of the arm. The symptoms of a dislocation are distortion and limited movement, with absence of the grating sensation felt in fracture when the extremities of a broken bone are rubbed together. The treatment consists in reducing the dislocation. The sooner this is done the better—the longer the delay the more difficult it becomes to remedy the displacement. After a variable period, depending on the nature of the joint and the age of the person, it may be impossible to replace the bones. The result will be a more or less useless joint. The administration of chloroform, by relaxing the muscles, greatly assists the operation of reduction. The length of time that a joint has to be kept quiet after it has been restored to its normal shape depends on its form, if osseously strong, then early movement is allowable, as in the elbow joint; if osseously weak, then early movement is unjustifiable. More especially is this the case when, associated with osseous

weakness, the strength of the joint is ligamentous, as in the sterno-clavicular and superior radio-ulnar articulations. In such joints the bones must be kept in accurate position and at rest for a lengthened period; if movement is allowed soon after the accident the bone will again slip out of its place.

DISMAL SWAMP, the name given to two extensive stretches of morass on the eastern seaboard of North America. The larger of the two, distinguished as the Great Dismal, lies in the peninsula between the James River on the north and Albemarle Sound on the south, and thus belongs partly to Virginia and partly to North Carolina. Its length from north to south is about 40 miles and its breadth about 25. The greater part of the area is covered with a thick stratum of spongy vegetable soil, without any mixture of earthy particles, which at once supports and is augmented by a luxuriant growth of aquatic plants, brushwood, and timber. The prevailing trees are cypress, juniper, and white cedar, and on the higher ridges oak and beech. By a curious arrangement, minutely described by Sir Charles Lyell in his *Travels in North America*, the surface of the swamp is actually higher, in some parts by as much as 12 feet, than that of the surrounding country; so that, except on the western side, where it receives a few small streams, the waters flow outwards. The centre is occupied by Drummond's Lake, an oval basin about 6 miles long and 3 wide, with perpendicular banks and an extreme depth of 15 feet; the water is clear and abounds with fish. The swamp has long furnished large supplies of timber, much of which has been obtained by excavation from the peaty soil in which it was preserved. The transit is facilitated by means of canals, of which the two most important are the Dismal Swamp Canal, uniting the western branch of Elizabeth river with the Pasquotank, and the Chesapeake and Albemarle Canal, connecting the eastern branch of Elizabeth river with Currituck Sound. The former is flanked by a stage road, which terminates in the south at Elizabeth City, and in the north at Norfolk. Two lines of railway pass through the outskirts of the Virginian portion of the swamp.

The Little Dismal is of much less importance. It lies in North Carolina, in the peninsula between Albemarle Sound and Pamlico Sound; and in the days when slavery was still legal, it was a noted harbour of runaway negroes.

DISPENSATION is a term used by the canonists to signify an act of jurisdiction by which the rigour of the general law is relaxed in a particular case. Regarded from this point of view a dispensation is considered by the canonists not to be an exception to, but a complement of, the law, and it is granted with discretion in cases where the law would otherwise work injustice. "*Fuit dispensatio inventa, ut esset pars distributivæ justitiæ.*" The exercise of this jurisdiction in the earlier days of the Christian church was vested in respect of minor matters in the bishops, and in more important matters in the provincial councils; but by degrees this latter jurisdiction came to be exercised by the patriarchs exclusively, and ultimately, in the case of the Western Church, by the Pope alone, who, at the time of the Reformation of the Anglican Church, had acquired for the Holy See supreme authority in all the more important matters of dispensation. It was one object of the Parliament of England, by the statute "concerning Peter Pence and Dispensations" (25 Henry VIII. c. 21), to divest the Pope of the exercise of any powers of dispensation within the realm of England, by forbidding the king and his subjects to sue to the Pope or to the Holy See for any dispensation. The Parliament further vested the power of granting dispensations, such as had been hitherto obtained from the see of Rome, in the archiepiscopal see of Canterbury—subject, however, to the

limitation that they should be only granted for such causes as were not contrary or repugnant to Holy Scripture or to the laws of the realm, and for this purpose the archbishop of Canterbury was empowered to constitute a sufficient commissary, and a clerk who should write and register all such dispensations. The representative of the clerk so appointed by the archbishop is the registrar of the office of faculties, over which the master of the faculties presides, as the archbishop's commissary. The matters for which dispensations were accustomed to be granted from the office of faculties, in the reign of Henry VIII., have almost all become obsolete, or have been withdrawn from the cognizance of the master of the faculties; and the special authority of his court in the present day consists in the grant of special licences for marriages, which are valid in both the provinces of Canterbury and of York, and the right of granting which has been preserved to the archbishop of Canterbury in all subsequent marriage Acts. These special licences are simply dispensations for the solemnization of marriage at other times and in other places than those to which marriage is restricted by the Anglican canon or by the statute law of the realm.

D'ISRAELI, ISAAC (1766–1848), was born at Enfield in May 1766. He belonged to a Jewish family which, having been driven by the Inquisition from Spain, towards the end of the 15th century, settled as merchants at Venice, and assumed the name which has become famous. In 1748 his father, then only about eighteen years of age, removed to England, where, before passing the prime of life, he amassed a competent fortune, and retired from business. Both he and his wife gradually dropped connection with their co-religionists, with whom their son never appears to have associated himself.

The strongly marked characteristics which determined D'Israeli's career were displayed to a singular degree even in his boyhood. He spent his time over books, and in long day-dreams, and evinced the strongest distaste for business and all the more bustling pursuits of life. These idiosyncracies met with no sympathy from either of his parents, whose ambitious plans for his future career they threatened to disappoint. At length, when he was about fourteen, in the hope of changing the bent of his mind, his father sent him to school at Amsterdam, where he remained four or five years. Here in the principal's library, and under the principal's influence, he studied Bayle and Voltaire, and became an ardent disciple of Rousseau. Here also he wrote a long poem against commerce, which he produced as an exposition of his opinions when, on his return to England, his father divulged his intention of placing him in a commercial house at Bordeaux. Against such a destiny his mind strongly revolted; and, in this extremity, it was natural that he should eagerly seek the sympathy and counsel of a literary friend. He carried his poem, with a letter earnestly appealing for advice and assistance, to Samuel Johnson; but when, full of eager hope, he called again a week after to receive an answer, the packet was returned unopened—the grand old censor was on his death-bed. He also addressed a letter to Dr Vicesimus Knox, in a tone of the loftiest sentiment, displaying all his literary aspirations, his earnestness and simplicity of heart, and his utter lack of all the qualities of "that despicable thing" (as he called him) "a mere man of the world," and begging to be received into the scholar's family, that he might enjoy the benefit of his learning and experience. How this application was answered we do not know. The evident firmness of his resolve, however, was not without effect. His parents gave up their purpose for a time. He was sent to travel in France, and allowed to occupy himself as he wished; and he had the happiness of spending some months in Paris, in the society of literary

men, and devoted to the literary pursuits in which he delighted

In the beginning of 1788 he returned home, being then a few months past his majority, to lay the first stone of his literary fame by an attack on Peter Pindar, under the form of a poem in the manner of Pope *On the Abuse of Satire*. Published, as it was, at a most appropriate moment, it at once attained popularity. Its authorship became the great subject of debate in literary circles, and it was attributed by some to Hayley, upon whom it was actually revenged, with characteristic savageness, by its victim. It is greatly to Wolcott's credit that, sensitive though he was to attacks upon himself, he at once, on learning his mistake, sought the acquaintance of his young opponent, towards whom he seems to have borne no malice, and whose friend he remained to the end of his life. But of all the fortunate issues of this success not the least fortunate was that it brought D'Israeli what he had so long earnestly desired—the friendship of a refined man of letters. Through it he made the acquaintance of Henry James Pye, who helped to persuade his father that it would be a mistake to force him into a business career, and who introduced him into literary circles. Henceforth his life was passed in the way he best liked—in quiet and almost uninterrupted study. His health was for the most part sufficiently robust, though he was for some years the victim of a nervous depression and weakness, which came upon him when he was about twenty-eight years of age, and which doubtless was chiefly caused by his sedentary habits. He was able to maintain his strenuous and extraordinary devotion to study till he reached the advanced age of seventy-two, when, though still in the enjoyment of unimpaired health, and in the very midst of what would have been his greatest undertaking, he was forced, by paralysis of the optic nerve, to give up work almost entirely. He lived ten years longer, and his death, which took place at his seat at Bradenham House on the 19th January 1848, was due not to old age but to an epidemic which carried him off after a few hours' illness.

Isaac D'Israeli is most celebrated as the author of the *Curiosities of Literature*, by far the best and most popular of all the many works of the kind which have appeared in England. It is a miscellany of literary and historical anecdotes, of original critical remarks, and of interesting and curious information of all kinds, animated by genuine literary feeling, taste, and enthusiasm. The first volume was published anonymously in 1791, and it immediately attained the popularity it deserved. Two years later it was followed by a second volume; it was not, however, till the lapse of twenty-four years that the third made its appearance. Three other volumes were subsequently added, and in the later editions the first two volumes were much improved. With the *Curiosities of Literature* may be appropriately classed D'Israeli's *Miscellanies*, or *Literary Recreations* (1796), the *Calamities of Authors* (1812), and the *Quarrels of Authors* (1814). Towards the close of his life D'Israeli formed the project of embodying his wide knowledge of English literature in a continuous history, loss of sight, however, prevented him from publishing more than three volumes, which appeared in 1841 under the title of the *Amenities of Literature*. But of all his literary works the most interesting and delightful is his *Essay on the Literary Character* (1795), which, like most of his writings, abounds in illustrative anecdotes. His contribution to the famous "Pope controversy"—in which Bowles and Hazlitt so vigorously attacked, and Byron and Campbell so vigorously asserted, the poetical merit and personal worth of the great poet of the 18th century,—a defence of Pope contained in a criticism of Spence's *Anecdotes* contributed to the *Quarterly Review* (July 1820)—is of interest,

both as indicating the nature of his critical views, and as founded upon elaborate study of the life and era of the poet. He also published a slight sketch of Jewish history, and especially of the growth of the Talmud, entitled the *Genesis of Judaism*, as well as a few poems in imitation of Pope, and several novels.

He was, besides, the author of two historical works—a brief defence of the literary merit and personal and political character of James I. (1816), and a work of considerable research and magnitude entitled a *Commentary on the Life and Reign of King Charles I.* (1828–31). The latter work was recognized by the University of Oxford, which conferred upon the author the honorary degree of D.C.L. As an historian D'Israeli is distinguished by two characteristics. In the first place, he had small interest in politics, and no sympathy with the passionate fervour, or adequate appreciation of the importance, of political struggles. And, secondly, with a laborious zeal then less common than now among historians, he sought to bring to light fresh historical material by patient search for letters, diaries, and other manuscripts of value which had escaped the notice of previous students. Indeed, the honour has been claimed for him of being one of the founders of the modern school of historical research, whose patient labours have thrown so much light upon important events and characters.

Of the amiable personal character and the placid life of Isaac D'Israeli a charming picture is to be found in the brief memoir prefixed to the *Curiosities of Literature*, by his son the earl of Beaconsfield, from which the following may be quoted.—Isaac D'Israeli "was a complete literary character, a man who really passed his life in his library. . . . He disliked business, and he never required relaxation; he was absorbed in his pursuits. In London his only amusement was to ramble among book-sellers; if he entered a club, it was only to go into the library. In the country he scarcely ever left his room but to saunter in abstraction upon a terrace, muse over a chapter, or coin a sentence. . . . He had by nature a singular volatility which never deserted him. His feelings, though always amiable, were not painfully deep, and amid joy or sorrow, the philosophic vein was ever evident. He more resembled Goldsmith than any man I can compare him to, in his conversation, his apparent confusion of ideas ending with some felicitous phrase of genius, his *naïveté*, his simplicity not untouched with a dash of sarcasm affecting innocence—one was often reminded of the gifted and interesting friend of Burke and Johnson. There was, however, one trait in which my father did not resemble Goldsmith; he had no vanity. Indeed one of his few infirmities was rather a deficiency in self-esteem."

DISTILLATION, a generic term for a class of chemical operations which all agree in this, that the substance operated upon is heated in a close vessel ("retort," "still") and thereby wholly or partially converted into vapour, which vapour is then condensed, by the application of cold, in another apparatus (the "condenser") connected with the vessel, and allowed to collect in a third portion of the apparatus, called a "receiver." In most cases the substance is a liquid, or assumes the liquid form previous to emitting vapours, and the product obtained (the "distillate") is also in greater proportion liquid. The comparatively few and special cases of distillation, wherein solids are converted into vapours which condense directly from the gaseous into the solid form, are designated "sublimations." Thus we speak of the "distillation" of water or of spirits, while we speak of the "sublimation" of sal-ammoniac. Distillations may be divided into two classes—viz, 1st, those which are *not*, and 2d, those which *are*, accompanied by chemical changes. The word "distillation," in a narrower sense, is generally understood to apply to the first class only. The

second might be called "destructive distillations," if it were not customary to reserve this term for the particular case in which the substance operated on consists of vegetable or animal matter which is being decomposed by the application of heat alone, *i.e.*, without the aid of re-agents.

The general object of simple distillation is the separation of substances of different degrees of volatility. The apparatus used varies very much according to the nature of the substance operated on and of the product extracted, and according to the scale on which the operation is carried out. Of the various contrivances used in chemical laboratories, the simplest is a glass retort, the descending neck of which is inserted into, and goes to near the bottom of, a slanting globular flask. The retort serves for the reception of the substance to be distilled, and is heated by means of charcoal or gas fire; the vapours pass into the flask, which is kept cool by a continuous current of cold water running over it, or, in the case of more volatile substances, by being immersed in ice or some freezing mixture. This somewhat primitive arrangement works satisfactorily only when the vapours are easily condensable, and when the product is meant to be collected as a whole. In the majority of cases, however, the distillate has to be "fractionated," *i.e.*, collected in a number of separate, consecutive portions; and it is then desirable that the apparatus should be so constructed as to enable one at any moment to examine the distillate as it is coming over. For this purpose it is necessary to condense the vapours on their way to, and not within, the receiver, so that the latter can, at any time, be removed and replaced by another. The condenser most generally used in chemical laboratories is that known as *Liebig's condenser*. It consists of a straight glass or metal tube, 1 to 3 feet long and $\frac{1}{4}$ to 1 inch wide, fitted co-axially, by means of corks or india-rubber tubes, into a wider tube (made of glass or iron) which communicates at the lower end with a water tap, and at the upper with a sink, so that a stream of cold water can be made to run *against* the current of the vapour. The condenser tube is fixed in a slanting position, and the vapours made to enter at the upper end. The dimensions of the condenser and rate of water-flow depend on the speed at which the vapour is driven over, and on the temperature of that vapour, and, last not least, on the *latent heat of the vapour* and *specific heat of the distillate*. To show the importance of the last-named point, let us compare the quantities of heat to be withdrawn from 1 lb of steam and 1 lb of bromine vapour respectively, to reduce them to liquids at 0° C. We have in the case of water and bromine—

	Water	Bromine.
For the temperature of the vapour	100°	63°
For the latent heat	536°	45° 6
For the specific heat of the liquids . .	1°	0° 106
For the total heats of the vapours	636°	52° 3

The withdrawal of 52.3 units of heat from 1 lb of bromine vapour reduces it to liquid bromine at 0° C. By the withdrawal of $\left(\frac{100}{63} \times 52.3 =\right)$ 83 units from the steam, as

an easy calculation shows, only 0.16 lb of liquid water, of even 100°, could be produced—hence *more* than 0.84 lb of steam remains uncondensed (at a temperature of about 96° C, assuming the steam to remain saturated, and to have the temperature of the condensed water). But obviously a condenser under all circumstances is the more efficacious the greater its surface and the thinner its body. It is also obvious, *ceteris paribus*, that the most suitable material for a condenser tube is that which conducts heat best. Hence a metal tube will generally condense more rapidly than one of glass, and for metal tubes copper is better than silver better than either. In chemical laboratories the only material which is quite generally appli-

cable. In chemical works, on the other hand, glass, on account of its fragility, is rarely used; condensers there, wherever possible, are made of metal, usually fashioned into spirals ("worms") and set in tub-shaped refrigerators. Where acids have to be condensed, stoneware worms are generally employed. In the distillation of acetic acid platinum worms, notwithstanding their high price, have been found to work best, and in the long run to be cheapest.

The theory and successful execution of the process assume their greatest simplicity when the substances to be separated differ so greatly in their volatility that, without appreciable error, one can be assumed to be non-volatile at the boiling point of the other. A good illustration of this special case is afforded by the customary process used for the purification of water. A natural sweet water may in general be assumed to consist of three parts—1st, water proper, which always forms something like 98 per cent or more of the whole; 2d, non-volatile salts; 3d, gases. To obtain pure water from such material, we need only boil it in a distillation apparatus, so as to raise from it dry steam, which steam when condensed yields water contaminated only with the gases. To expel these all that is necessary is to again boil it for a short time, the gases go off with the first portions of steam, so that the residue, when allowed to cool in absence of air, constitutes pure water. To pass to a less simple case, let us assume that the substance to be distilled is a solution of ether in water, and the object is the separation of these two bodies. Ether boils at 35° C, water at 100° C. The elastic force of saturated steam at 35° is 42 mm, $= \frac{42}{760} = \frac{1}{18}$ th of an atmosphere. Assuming now the mixture to be distilled from a flask, what will go on? Neglecting for the sake of simplicity the small tension of the steam at 35°, we should expect that at first the ether would simply boil away, so to speak, from a bath of warm water at 35° C.; that the vapour would be pure ether, and maintain that composition until all the ether had boiled off, then there would be a break—the temperature of the liquid would gradually rise to 100°, and the water then distil over in its turn. And so it is approximately, but not exactly. Our theory obviously neglects some important points. Water at 35° has a tension of $\frac{1}{18}$ th atmosphere, ether of one atmosphere, hence the two saturated vapours together should press with a force of $1\frac{1}{18}$ th atmosphere—in other words, the mixture should commence to boil at less than 35°. This, however (as in the majority of analogous cases), is not confirmed by experiment. The mixture commences to boil at a little above 35°, and the boiling point rises *steadily* as the proportion of ether in the liquid decreases. Now, *a priori*, we should presume that at every given moment the volumes of ether and water in the vapour should be, approximately at least, proportional to the respective vapour tensions at the temperature at which the mixture happens to boil. Thus, for instance, assuming at the first that the liquid boils at 40° C., when the two tensions are equal to 910 and 55 mm. respectively, the vapour will contain $\frac{910}{910+55} = 0.94$

of its volume of ether vapour, and 0.06 of its volume of steam, supposing both substances to have the same chances of forming saturated vapour, which, of course, holds only so long as they both are present in appreciable quantities. We easily see that, as the distillation progresses, the ether vapour must get more and more largely charged with vapour of water, until at last what goes off is *steam*, contaminated with less and less of ether vapour. A thermometer placed near the entrance end of the condenser will, of course, record lower than one plunged into the boiling liquid, because the vapour in rising undergoes partial condensation, and the thermometer being belated with the condensed vapour will approximately indicate the

boiling point of that dew, *i.e.*, of that which is just going over. The composition of the vapour as above given must not be confounded with the composition by *weight* of the distillate. To obtain the latter we must multiply each of the two volumes by the density of the respective vapour, or, what comes to the same thing, by its molecular weight as expressed by the chemical formula. In our case the vapour volume ratio

$$\frac{\text{water}}{\text{ether}} = \frac{55}{910}$$

corresponds to the weight ratio

$$\frac{55 \times \text{H}_2\text{O}}{901 \times \text{C}_4\text{H}_{10}\text{O}} = \frac{55 \times 18}{910 \times 74} = \frac{1}{68} \text{ nearly}$$

This consideration strips of its apparently anomalous character what we observe when vegetable substances containing essential oils are distilled with water, when we find that these oils, although boiling far above 100°C , go over with the first fractions of the water. Take the case of lemon oil, which boils at about 174°C . The molecular weight of the oil is $136 = \text{C}_{10}\text{H}_{16}$; its vapour tension at 100° is 70 mm. Hence what goes over at first when lemon peel is distilled with water should contain oil and water in the proportion—

Oil of Lemons		Water	
Mol. wt.	Vap. tension	Mol. wt.	Vap. tension
136	70	18	760
$\times 70$		$\div 760 = 12$	
		17 (nearly)	

The oil, although the less volatile substance of the two, being present in small quantity, but finely diffused, is soon completely driven over. No doubt the latent heats of vaporization of the two constituents have something to do with the composition of the vapour formed, as the chance of every particle of the mixture to be vaporized is obviously the greater the less its latent heat of vaporization.

After what has been said it will be clear that in the distillation of a mixture of two substances of approximately equal molecular weight and latent heats of vaporization, supposing neither to predominate overwhelmingly over the other, the one with the lower boiling point will predominate in the early, and the other will gradually accumulate in the later, fractions of the distillate. And similarly with mixtures of three or more bodies. The further the respective boiling points are removed from one another the more complete a separation can be effected; but in no case is the separation perfect. It is, however, easily seen that the analytic effect of a distillation can be increased by causing the vapour, before it reaches the condenser, to undergo *partial* condensation, when naturally the less volatile parts chiefly will run back. This artifice is largely employed by chemists, technical as well as scientific. The simplest mode is to let the vapour ascend through a long, vertical tube before it reaches the condenser, and to distil so slowly that a sufficiently large fraction of the vapour originally formed fails to survive the ascent through the cooling influence of the atmosphere. A more effective method is to let the condensed vapour accumulate in a series of small receptacles inserted between flask and condenser, constructed so that the vapour cannot pass through the receptacles without bubbling through their liquid contents, and so that the liquid in the receptacles cannot rise above a certain level, the excess flowing back into the next lower receptacle or into the still. But the most effective method is to let the vapour ascend through a slanting condenser kept by means of a bath at a certain temperature, which is controlled so that while the liquid in the flask boils rapidly, the distillation only just progresses and no more.

The general principles thus stated regarding fractional distillation are liable to not a few exceptions, of which the

following may be cited as examples. A solution of one part of hydrochloric acid gas in four parts of water boils (constant) at 110°C .—*i.e.*, 10° above the boiling point of water, although the acid constituent is an almost permanent gas. This, however, is easily explained: there can be no doubt that such an acid is a mixture of real hydrates, *i.e.*, does not contain either free water or free hydrochloric acid. A similar explanation applies to the case of aqueous oil of vitriol, which boils the further above 100° the stronger it is, although the vapour may be, and in the case of acids containing less than 84 per cent. of real acid really is, pure steam. The following cases, however, can scarcely be disposed of by the assumption of the interference of chemical action. Propyl alcohol boils at 97°C , water at 100° , and yet a mixture of the two, as Pierre and Puchot found, when distilled always commences to boil at $88^\circ 5$ with formation of a distillate of the approximate composition $\text{C}_3\text{H}_8\text{O} + 2.78\text{H}_2\text{O}$, and this particular aqueous alcohol boils without apparent decomposition at $88^\circ 3$. Some time later Dittmar and Steuart made a precisely analogous observation with regard to aqueous allyl alcohol. A strong temptation exists to explain these anomalies by the assumption of definite hydrates in the aqueous alcohols, and this hypothesis would serve in the meantime were it not for the curious fact, discovered by the two French chemists named, that amyl alcohol and water (two liquids which *do not mix*), when distilled simultaneously out of the same retort, go over at a constant temperature less than 100° , and with formation of a distillate which, although it is not even a mixture, has a constant composition. The most natural explanation of these phenomena is to assume them to be owing, not to chemical action, but rather to an exceptional absence of chemical affinity between the two components of the mixture, which for once gives the physical forces fair play.

DRY (DESTRUCTIVE) DISTILLATION.—Of the great number of chemical operations falling under this head, we can notice only those which are carried out industrially for the manufacture of useful products. Of such the most important are those in which wood, coal, shale, and bones form the materials operated upon. But as these processes form so many important industries, which have all special articles devoted to them, we must confine ourselves here to summing up shortly the features common to all.

In all cases the "retorts" consist of iron or fire-clay semi-cylinders placed horizontally in a furnace and connected by iron pipes with refrigerators, and through these with gas-holders. Within these retorts the materials are brought up, more or less gradually, to a red heat, which is maintained until the formation of vapours practically ceases. Each of the materials named is a complex mixture of different chemical species. Wood consists mainly of cellulose and other carbo-hydrates, *i.e.*, bodies composed of carbon and the elements of water, in coal and shale the combustible part consists of compounds of carbon and hydrogen, or carbon, hydrogen, and oxygen, richer in carbon than the components of wood, bones consist of about half of combustible and infusible phosphate of lime (bone earth) and half of organic matter, of which the greater part is gelatine (compounds of carbon, nitrogen, hydrogen, and oxygen), and the lesser is fat (compounds of carbon, hydrogen, and oxygen). The chemical decomposition in each case is highly complex. An infinite variety of products is invariably formed, which, however, always readily divide into three:—1st, a non-volatile residue, consisting of mineral matter and elementary carbon ("wood charcoal," "coke," &c) which, in the case of animal matter, contains chemically combined nitrogen, 2d, a part condensable at ordinary temperatures which always readily separates into two distinct layers, *viz.*—(a) an aqueous portion ("tar-water"), and (b) a semifluid, viscous,

oily, or resinous portion ("tar"); and 3d, a gaseous portion.

The "tar-water" is the one, of all the four products, of which the qualitative composition most directly depends on the nature of the material distilled. In the case of wood it has an acid reaction, from the presence in it of acetic acid, which is associated (amongst many other things) with acetone and methyl alcohol. In the case of coal it is alkaline, from ammonia, present as carbonate, sulphide, sulphocyanide, and in other forms. Alcohols and oxygenated acids are absent.

The "tar" is a complex mixture of carbon compounds, all combustible, but, although all directly derived from a vapour, not by any means all of them *volatile* (Regarding the components, see *TAR*.) The quantity and quality of the tar naturally depend on the kind of material used, but perhaps yet more on the mode in which the distillation is conducted. Thus, for instance, a coal tar produced at low temperature contains a considerable percentage of paraffins. If, on the other hand, the distillation is conducted at a high temperature, the paraffins are almost absent, while the proportion of benzols considerably increases. A similar remark applies to the gaseous portion, as will readily be understood when we say that *all* volatile tar constituents, when passed through red hot tubes, are decomposed with formation of hydrogen and gaseous hydrocarbons, which latter again, when submitted to the same operation, are all liable to undergo dissociation into simpler compounds and association into more complex.

DISTILLATION OF WATER.—The continual interchange and circulation of water, between oceans and other great reservoirs of water on the one hand and dry land on the other, may be regarded as a process of distillation. Rain is thus a form of distilled water; and when it falls through a pure atmosphere it is found to possess the softness and freedom from dissolved salts characteristic of water artificially distilled. Rain water, however, absorbs a considerable proportion of air and some carbonic acid from the air, and also frequently contains ammonia, salts, and free acids.

Water of that purity which can be secured only by distillation is of indispensable value in many operations both of scientific and industrial chemistry. The apparatus and process for distilling ordinary water are very simple. The body of the still is made of copper, with a head and worm, or condensing apparatus, either of copper or tin. The first portion of the distillate brings over the gases dissolved in the water, ammonia, and other volatile impurities, and is consequently rejected, and scarcely two-fifths of the entire quantity of water can be with safety used as pure distilled water.

Among the innumerable schemes which have been proposed for the production of a potable fresh water from the salt water of the ocean, two or three dependent on simultaneous distillation and aeration have been found, in practice, to produce most satisfactory results. Of course the simple distillation of sea water, and the production thereby of a certain proportion of chemically fresh water, is a very simple problem; but it is found that water which is merely evaporated and recondensed has a very disagreeable empyreumatic odour, and a most repulsive flat taste, and it is only after long exposure to pure atmospheric air, with continued agitation, or repeated pouring from one vessel to another, that it becomes sufficiently aerated to lose its unpleasant taste and smell and become drinkable. The water, moreover, till it is saturated with gases, readily absorbs noxious vapours to which it may be exposed. For the successful preparation of potable water from sea water, therefore, the following conditions are essential:—1st,

aeration of the distilled product so that it may be immediately available for drinking purposes; 2d, economy of coal to obtain the maximum of water with the minimum expenditure of fuel, and 3d, simplicity of working parts, to secure the apparatus from breaking down, and enable unskilled attendants to work it with safety. Among the forms of apparatus which have most fully satisfied these conditions are the inventions of Dr Normandy and of Chaplin of Glasgow. While these have met with most acceptance in the United Kingdom, the apparatus of Rocher of Nantes, and that patented by Gallé and Mazeline of Havre, have been highly appreciated by French maritime authorities.

Normandy's apparatus, while leaving nothing to be desired in point of economy of fuel and quality of water produced, is very complex in its structure, consisting of very numerous working parts, with elaborate arrangements of pipes, cocks, and other fittings. It is consequently expensive, and requires for its working the careful attention of an experienced workman. It consists of three essential parts, in addition to any convenient form of boiler from which steam under a certain amount of pressure may be obtained. These parts are called respectively the evaporator, the condenser, and the refrigerator. These are all closed cylindrical vessels, permeated internally with sheaves of pipes, through which pipes the steam generated percolates, condenses, and is aerated as explained below. The refrigerator is a horizontal vessel above which the condenser and the evaporator are placed in a vertical position. When the apparatus is in operation the refrigerator and condenser are filled with sea water, and a constant current is maintained which enters by the refrigerator, passes upwards through the condenser, and is discharged by an overflow pipe at a level a little above the top of the condenser. The evaporator is filled only to about two-thirds of its height with water from the condenser, and the admission and regulation of its contents are governed by a stop-cock on the pipe communicating between the two vessels. The vessels being so prepared, superheated steam is admitted by a pipe leading from the boiler into the top of the evaporator, and, passing through the sheaf of pipes immersed in water, is there condensed. The condensed water passes direct from the evaporator into the pipes of the refrigerator, in which it is cooled to the temperature of the surrounding sea water. Here then is produced pure distilled but non-aerated water, and the means by which it is aerated and rendered fit for immediate use may be now traced. The superheated steam in permeating the pipes in the evaporator heats and vaporizes a portion of the water around them. The steam so generated passes into the sheaf of pipes in the condenser, in which, as already explained, a current of water is constantly rising and passing away by the overflow pipe. The condensation of the steam within the pipes, again, communicates a high temperature to the upper stratum of water in the condenser. As water at a temperature of $54^{\circ} 5^{\circ} \text{C}$ parts with its dissolved air and carbonic acid gas, a stream of water is continually rising to the upper part of the condenser at a temperature more than sufficient to liberate these gases, and by means of a pipe these pass over into the upper part of the evaporator, and there mingle with and supersaturate the steam generated in that vessel. Instead, therefore, of it being simply steam which passes from the evaporator to the tubes of the condenser, it is a mixture of steam and gases, the latter being in sufficient quantity not only to supersaturate the steam with which they are mixed, but also fully to aerate the condensed steam which passed direct from the evaporator into the refrigerator. The super-aerated condensed steam passes from the pipes in the condenser into those in the refrigerator, where it meets the

non-aerated water from the evaporator pipes, the course of which has already been traced. Here the two products mingle, cool down to the temperature of the sea, and passing outwards through a filter, may be drawn off as pure aerated water of excellent quality. In Dr Normandy's apparatus the combustion of 1 lb of coal yields from 14 to 20 lb of potable water. The apparatus is extensively adopted in the British navy, the Cuaard line, and many other important emigrant and mercantile lines.

Chaplin's apparatus, which was invented and patented later, has also, since 1865, been sanctioned for use on emigrant, troop, and passenger vessels. The apparatus possesses the great merit of simplicity and compactness, in consequence of which it is comparatively cheap and not liable to derangement. In addition to a boiler for generating steam from sea water the apparatus consists of an aerator, a condenser, and a filter. The condenser is a cylinder, usually of cast iron with an internal worm pipe of copper, which is found to be the only really suitable metal for this use. The steam to be condensed is admitted to this worm or coil through the aerator. This part of the apparatus—the aerator—is really the essential feature in the invention, and consists simply of a series of holes perforated around the steam inlet pipe at the point where it enters the condenser. The steam passing down in a powerful jet draws with it through these holes a proportion of atmospheric air sufficient to properly aerate the water for drinking purposes. The steam and air thoroughly commingled are together condensed as they pass through the coils of the worm,—cold sea water passing in to the condenser at its lowest end, and rising upwards and flowing away at the top. After passing through the filter placed directly under the condenser, the aerated water is delivered or stored ready for use, clear, bright, colourless, palatable, and devoid of odour, at a temperature of about 15° C. The cold sea water for condensing may be forced into the condenser by a special steam pump attached to the apparatus—a plan usually followed on sailing vessels—or any other convenient pumping arrangement may be resorted to. The steam for condensation is, in steamers, frequently supplied from the engine boilers; but generally it is preferable to employ a special small upright boiler, or to use the boilers attached to steam winches. Chaplin's apparatus has been adopted by many important British and Continental shipping companies, among others by the Peninsular and Oriental, the Inman, the North German Lloyd, and the Hamburg American Companies.

DISTILLATION OF SPIRITS.—Notwithstanding the enormous scale on which this industry is now prosecuted, it is only in modern and comparatively recent times that it has attained to the important position which it now occupies. The art of separating alcoholic spirit from fermented liquors appears, however, to have been known in the far East from the most remote antiquity. It is supposed to have been first known to, and practised by, the Chinese, whence a knowledge of the art gradually travelled westward. A rude kind of still, which is yet employed, has been used for obtaining ardent spirits in Ceylon from time immemorial. The name alcohol indicates that a knowledge of the method of preparing that substance probably came to Western Europe, like much more chemical knowledge, through the Arabs. Albucaasis, who lived in the 12th century, is spoken of as the first Western philosopher who taught the art of distillation as applied to the preparation of spirits; and in the 13th century Raymond Lully was not only well acquainted with the process, but also knew the method of concentrating it into what he denominated *aqua ardens* by means of potassic carbonate. At the time when Henry II.—in the 12th century—invaded and conquered Ireland, the inhabitants were in the

habit of making and using an alcoholic liquor—*uisge-béatha*, water of life), a term since abbreviated into whisky, which consequently is synonymous with the classical *aqua vitæ*. It is further a noticeable fact that Captain Cook found, among the inhabitants of the Pacific Islands discovered by him, a knowledge of the art of distilling spirit from alcoholic infusions.

The preparation of ardent spirit involves two separate series of operations:—1st, the making of an alcoholic solution by means of vinous fermentation, and 2d, the concentration of the alcoholic solution so obtained by the process of distillation and rectification.

All substances in nature which contain sugar in any of its forms are susceptible of undergoing vinous fermentation, and may therefore be used as sources of alcohol. Further, all starchy substances and ligneous tissue, seeing that by various chemical processes starch and cellulose may be converted into grape sugar, may also be used for the preparation of alcohol. It is thus obvious that the variety of organic substances, especially of the vegetable kingdom, from which alcohol may be elaborated is almost endless; and in practice it is found that the sources employed are very numerous. Commercially, distilled alcoholic liquors are manufactured of varying strength, or proportion of alcohol to water, according as the spirit is intended to be used for drinking purposes or for employment in the arts. The standard by which excise duty on alcoholic liquor is charged in Great Britain is proof spirit, in which the alcohol and water are in almost equal proportions by weight, there being in 100 parts 49.24 of absolute alcohol, and 50.76 of water. Distilled spirits are said to be "over proof" when the proportion of alcohol is greater, and "under proof" when there is more water present than is indicated by "proof." Thus a spirit 11 over proof (o.p.) is a compound which requires the addition of 11 volumes of water to every hundred to reduce it to proof strength; and similarly 10 under proof (u.p.) indicates a liquor from every 100 gallons of which 10 gallons of water must be withdrawn to bring it to proof strength. Spirit for drinking is seldom sold at more than 11 over proof, from which it varies downward to 25 and more under proof. Rum, however, is manufactured and imported as highly concentrated as from 10 to 43 over proof. Spirit of wine as used in the arts must be at least 43 over proof, and generally it is sold at from 54 to 64 over proof.

The alcoholic liquors enumerated below are those most commonly distilled for drinking or medicinal purposes. Brandy, when genuine, is a spirit chiefly distilled in France from wine. Rum is made from molasses or treacle, and is distilled in the West Indies, and generally in all countries where the sugar cane is cultivated. From fermented infusions of grain, malted and unmalted, and chiefly from barley, whisky is distilled, and that spirit when "silent" or flavourless is the basis of flavoured spirits, such as gin and factitious or British brandy. Arrack is an Oriental spirit distilled from "toddy," or the fermented juice of certain palm trees, and also from rice, which grain is the source of saké, the national spirit of the Japanese. Potato brandy is very extensively prepared from the fecula of potatoes in Germany and Russia, and is a spirit much used for fortifying wines, and for making factitious wine, as well as in the arts. Beet root, carrots, Jerusalem artichokes, and several other saccharine roots are also used for the distillation of spirit on a commercial scale. The only example of a spirit drawn from animal sources is the koumiss of the Tartars, which is distilled from the fermented milk of mares.

The modifications of stills or of distilling apparatus used in the preparation of alcoholic liquor are exceedingly numerous, and many of the later inventions are of most

complicated structure. The simple and primitive varieties of apparatus yield only a comparatively weak spirit on the first distillation, while the effect of the complex appliances now generally used is to produce, in one operation, a highly concentrated spirit, and that with a great saving of fuel, time, and labour. All varieties of distillatory apparatus resolve themselves under these heads—1st, stills heated and worked by the direct application of the heat of a fire; 2d, stills worked by the action of steam blown direct into the alcoholic solution from a steam boiler; and 3d, stills heated by steam passing in coiled pipes through the alcoholic solutions to be acted upon.

To the first of these classes—stills heated by direct fire—belong the earliest and simplest forms of distillatory apparatus; and for producing particular classes of alcoholic liquor, stills very simple in their construction are yet employed. The common still is a flat-bottomed, close vessel of copper, with a high head to prevent the fluid within boiling over. To the top of this head a tube is connected, which is carried in a spiral form round the inside of a tub or barrel (the condenser or refrigerator), filled with cold water, and from its twisted form this tube receives the name of the “worm.” The tube terminates at the bottom of the barrel, passing through it to the outside, and is conducted into the vessel termed the receiver, a stopcock, or more commonly a vessel termed a “safe,” being usually placed on the tube where it leaves the refrigerator. In distilling with an apparatus of this simple construction, it is obvious that at the beginning of the operation, when the wash or liquid to be distilled is rich in alcohol, and its boiling point consequently low, the distillate will pass over at a low temperature and contain a high percentage of alcohol. But as the operation progresses, the boiling point of the mixture in the still rises, the heat has therefore to be forced, and the quantity of watery vapour which passes over with the alcohol is proportionately increased. As the wash or liquid in the still continually weakens, a point is arrived at when the value of the weak distillate produced will not balance the expenditure on fuel for maintaining the heat of distillation.

One of the earliest devices for economizing the heat of distillation consisted in interposing between the still and the refrigerator a wash warmer, or vessel charged with liquid ready for distillation. Through this vessel the pipe conveying the hot vapours to the refrigerator coil passed, and the vapours, partly condensing there, heated up the wash, which was thus prepared to pass into the still at an elevated temperature. The “pot” stills, in which the markedly flavoured Irish whisky is made, are of this construction. In the great establishment of the Banagher Distillery Company, King’s co., Ireland, simple stills of a capacity of 20,000 gallons are erected having a rousing apparatus within them to keep the wash in agitation so as to prevent solid particles from settling on the bottom and burning. Beyond a wash warmer, or intermediate charger interposed between the still and the condenser, there is no other appliance attached to the apparatus. The first distillate from the still is termed “low wines,” and passes into the “low wines receiver,” whence it passes into No 1 “low wine still” to undergo a second distillation. The product of the second distillation, under the name of “faints or feints,” is caught in the “faints receiver,” from which it passes to No 2 low wines still, and from this it is discharged as Irish whisky.

The introduction of another principle into distillatory apparatus is illustrated by Dorn’s still, which was introduced into Germany in the early part of the century, and is yet much used in smaller establishments in that country. In that apparatus the vessel, of copper, interposed between the still and the condenser is divided horizontally into two

unequal compartments by a diaphragm of copper. The upper and larger portion acts as a wash warmer (German, *Vorwärmer*), and through it the pipe from the still body coils, opening into the lower division. For a time the whole distillate condenses in this division, but as the temperature of the wash in the upper division rises, and the heat of the more watery distillate from the still also increases, the condensed liquor in the lower division in its turn begins to boil, and undergoes a second distillation or rectification, the vapours from it passing onwards to be condensed in the ordinary refrigerator. In many forms of distillatory apparatus two or more such rectifiers are placed between the primary still and the final condenser. The principle of the rectifier is easily understood. Supposing the operation of distilling to commence, the vapours which condense in rectifier No. 1 are much richer in alcohol than the liquid remaining in the still. The boiling point of the condensed liquid is consequently proportionately lower, and the vapour from the still passing into it gradually raises it to the boiling point, so that in its turn rectifier No. 1 distills into rectifier No 2 a liquid of still higher alcoholic richness. The relation of No. 2 to No 1 is the same as that of No. 1 to the still body, and thus the concentration and redistillation might be carried on to any practicable or desired extent.

Another principle brought into play in complex stills for the separation of stronger from weaker alcoholic solutions consists of dephlegmation, or the submitting of the vapour to a temperature so regulated that a portion of it, and that of course the most watery, is condensed and separated, running back into the still or into a special vessel, whilst the richly alcoholic vapour passes on to the rectifier or condenser. In Dorn’s still the wide and lofty head attached acts as a dephlegmator, watery vapours condensing on it, and thence falling back into the body, but in the more recent forms of apparatus—such as those of Pistorius and Siemens—special dephlegmators of an elaborate nature are introduced.

Of the second class of stills—those in which the operation is conducted by the heat of steam generated in a boiler, and forced into the apparatus—the Coffey still may be taken as an example. It is the form most frequently adopted in Great Britain for the manufacture of “silent” spirit, and it is generally recognized as the best and most economical device for preparing a highly concentrated spirit in a single operation. The Coffey still may further be regarded as a type of continuous distilling apparatus, as in it the necessity for withdrawing exhausted solutions and recharging the still with fresh wash is avoided. Beginning, as the Coffey still does, with the steam of pure water, the principle of rectification formerly alluded to is here carried out from the first step. The watery vapour becomes more and more highly charged with alcoholic fumes, till in the end the strongest spirit falls, condensed, into the receiver. In Coffey’s apparatus the wash is exposed in a series of shallow chambers, placed one over the other, to the vapour of steam, which rises through the perforated bottoms of each chamber, and carries off the alcoholic vapours into the condenser. This condenser also consists of a series of chambers separated from each other by perforated plates, and is so contrived that the cold wash passing in pipes through these chambers, in its way to feed the other series of chambers, acts as the condenser to the vapour of the alcohol, the wash being gradually heated thereby, as it passes through the successive chambers. The still, therefore, consists essentially of three separate but connected parts. The first is a large square receiver at the base, which receives the spent wash after it has been deprived of its alcohol by passing through the series of evaporating chambers: the second, a large, square, upright

box, termed an "analyzer," contains the series of evaporating chambers, each communicating with the one below by means of a valved tube, which allows fluid to escape from the upper to the lower chamber only, and having the dividing partition of each chamber perforated with fine apertures, to allow the steam which is admitted from below to pass from chamber to chamber through the shallow layer of wash of each. A safety or escape valve is also fitted to each chamber. The already heated wash enters the uppermost of these chambers in a continuous regulated stream, is gradually deprived of its alcohol by the steam as it passes from chamber to chamber, and at last escapes into the lower large receiver, from which it flows off after attaining a certain depth. The third part of the apparatus also consists of a square upright box, termed a "condenser," divided into compartments by means of finely perforated plates, and in each chamber is a link of the tube which carries the cold wash onwards to supply the evaporating chambers just described. The alcoholic vapours escaping from the uppermost of the evaporating chambers are carried by pipes to the lowermost of these chambers, and are partly condensed by each successive chamber being colder than the one below it, in consequence of the wash entering the pipes from above, and only getting gradually heated by contact with the alcoholic vapour as it advances from chamber to chamber. As in the lowest of these chambers the heat is greatest, the alcoholic vapour or the condensed spirit contains a large amount of water; but as the chambers are successively cooler, the alcoholic vapour and condensed spirit at last arrive at a temperature only sufficient to convert spirit of the strength wished into vapour, and by an adaptation of valves, the substitution of an impervious partition for the perforated plate, and the admission of the alcoholic vapour into the chambers cooled by the passage of the cold wash in its contained pipes, that spirituous vapour is condensed, and the spirit is drawn off at one operation, of the very strength which it ought to have, and of the utmost purity.
